3043. Small Mobile antenna for 7 MHz. Anyone built one?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-14 00:00:00 UTC
From: waboo@cltr.uq.oz.au
Message-ID: <3u4jf6$crh@dingo.cc.uq.oz.au>
Source record: 111852

I have made several mobile antennas for 7MHz and they have all worked well. I have also modified commercial antennas and they have worked well too. What I need though is a short version of what I have built. It finished article needs to be only about 1 merte long. The reason? so I can get into my garage without having to get out and take the antenna off. I have mounted it on my tow bar and brought a section of water pipe up to clear the boot then I place the whip on top of that. So the sp[ace I have left is about 1 metre. Any ideas.

Grungy Math Deleted.

>Dave Kirkby G8WRB.

>PS

The equations that you quote allow you to translate impedances from
the input plane to the output plane, and vice-versa. In other words,
if you have a known load impedance, you can use those equations to go
and calculate the input impedance that your device will present. Then,
you can take that input impedance and design a conjugate match for
that.

Going the other way, if you want to match for NFmin, you could
calculate what the output impedance is going to be.

I hope this is clear.

I thing that you are looking for a simultaneous conjugate match, which
is done with another set of equations. I would reccomend hitting the
library for a book by Gonzalez, entitled "Microwave transistor
Amplifiers."

Message-ID: <DJCH.95Jul14083558@tamar.dra.hmg.gb>
Source record: 111854

I saw a note once which suggested that the VN66AF was a development of the VMP4. True or not, I have built a 50 MHz linear amp with a VN66AF driving two VN66AF's in push-pull. Output is 10W (+40dBm) PEP, and 3rd order products are around 27 db down from the peak, suggesting 3rd order intercept about +53dBm. I've not measured the noise figure. Power supply is +24V, devices biased to 150mA standing current. Gain is 12-14 dB per stage.

Hope this helps, ask me for more details.

3046. re: crystal source

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-14 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <52b_9507141714@mba.mba.org>
Source record: 111855

spearce@ccu1.auckland.ac.nz was looking for a source of
1.8432MHz crystal to build the spectral display in the ARRL
Handbook.

This should be a very easy to get crystal. Properly divided,
the frquency supplies the common baud rates for serial
communications, which means the crystals are everywhere. It's
also why it's used in that spectral display; ata quick glance,
it's being used to supply the clock to get the signal out of
there in a serial format. The fact that the crystal is cheap
and easy to get probably determined that it was used too; other
frequencies can supply the proper clock rates, but this might
be the most common choice.

A lot of electronic component catalogs here in north america
have a section of commonly used crystals; these are the types
used in computers and serial ports and such. I'd check one of
those. If for some reason New Zealand doesn't have distributors
like that (here in Canada we have them, but it's not like we're
overflowing with sources of electronic components), surely you
could get one from Australia.

Another place to look would be in old computer junk. It is a
common frequency. Many boards with a serial port for IBM
compatibles would have such a crystal. I was at a yard sale
a month ago, and got a box of such boards for a dollar. I have
a use for them, so I wouldn't scrap them for just a crystal. But
I know that if I was desperate, I would take the crystal off the
board and later replace it when I was able to find a source of
crystals. So you would find one there. I just noticed in
looking at two boards that one of them uses an 18.432 MHz
crystal, ie ten times higher, for some reason. Make sure the
decimal is in the right place.

You should be able to find those boards all over the place.
Check the garbage maybe. I've found boards for the old Apple II
that way, and one of them was a serial board with the desired
frquency. Or check a place that repairs computers. In a lot
of places, boards are simply replaced instead of repaired. Maybe
you could get an old board labelled broken, and get the crystal
off it.

I hope this helps. The crystals are very readily available.
Don't pay much for them, because they are nice and cheap.

VINTAGE EQIUPMENT FOR SALE

1)Vintage Viking Challenger Cw transmitter modified for AM also. Included is VFO and a few crystals.

2) Lafayette HA800b receiver

3) Heathkit SWR/Power meter.

It has not been years since the equipment has been fired up. There should be essentially nothing wrong with any of the above equipment.

Equipment gos to the highest bidder.

Please E mail me back with questions or a quote if your interested.

Thanks

Carl Scarpa
cgs@asl.hitachi.com

Posting-Frequency: posted on the 15th of each month

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Hi Jake,
I would need more information about your applicaton, before I would
make any reccomendations. Send E-Mail. Your address bounced.
The usual squelch circuit in an FM reciever is to look at the energy ABOVE
the voice range (?Super-sonic?). When this energy drops it is usually
because of the presence of a recieved station. THe circuit can then be
modified to include the voiced energy band for tone decode etc.

When you mention an amplifier, I suspect you DON'T mean squelch.
But, I've been wrong before... I can still remember when...

Four or five years ago RadCom had an article about high-performance DC Rxs
which included a well-isolated RF amp, I think, to prevent the LO getting
back into the antenna.

Better yet, use a Philips BF904 dual gate MOSFET, with gate 2 at RF ground.
You can get 40 or 50 dB. isolation with some forward gain.

Another approach is to use a grounded base amplifier with the base grounded
only thru a series resonant 82 MHz. tank.

Message-ID: <1db.3465.4478@psl-online.com>
Source record: 111861

Hello, everybody.

I have an old top-of-the-line Sony TC-135SD cassette deck. Although it's cassette features still work, I guess the most valuable feature it has now is the 'limiter.' With it switched, and the rec. level slider pumped up, it does a good job at compressing the dynamic range. It's easily connected through RCA line in/out plugs.

Any interested parties please make bids, or have any questions, please contact:

I'm looking at the latest QST at the "Rock-Bending Receiver for 7 MHz" article by Randy Hnederson, WI5W. He has the collector of the crystal oscillator directly connected to pin 7 of the mixer and feeds pin 8 with V+. This results in the DC current of the oscillator flowing through the mixer LO transformer. The current is about 20+ mA. How much current is OK to run through here? At what point does the RF transformer in the mixer start having problems (saturation?)?

Gary -- You've got a sense of humor as well as being technically
correct. That is rare in we techie types and I really appreciate
reading the stuff you post.

If you wind the primary of the tesla coil with finer gauge wire than
the 1/2" copper tubing you recommended in your post (say, for example,
some #22 enameled wire) you can drive it with any of the popular TV
horizontal sweep tubes -- not quite as much poo at the output, but
maybe a little easier to find the parts, not to mention the power
transformer doesn't have to be the size of a pole pig!

><rickcrider@aol.com>

To build a Jacob's ladder the quick and dirty way is to find a Model T Ford ignition coil (They still make them and they're available from antique car parts places -- maybe you can find one listed on the internet)

You also need a source of 6-12 Volts DC for the coil.

Take two #10 or #12 bare copper wires about 1-2 feet long. Connect one to each of the high voltage terminals of the coil. Arrange the two wires in a very gradual V with a spacing of about 1/2 inch at the bottom and as wide as practical (1-1.5 inches) at the top. Power up the coil; standing well back from the apparatus.

CAUTION!!! (YES, I KNOW I'M YELLING) KEEP AWAY FROM THE HV TERMINALS. THE POWER OF THE COIL CAN HURT YOU AND AT IF YOU ARE LUCKY WILL KNOCK YOU ON YOUR #!&^%$#.

The ladder works as follows:

The arc generates heat (Lots of it) which causes it to rise until the spacing between the conductors breaks the arc. A new arc then forms at the bottom and proceeds upward. Sometimes if there is a lot of power you can get a couple of arcs going, but generally only one.

The ignition coil has an adjustment screw to help optimize the output of the device. You can play with it to tune the apparatus.

Please -- BE CAREFUL and have fun.

I saw a reference to a neon sign transformer which will work just fine. However, it has even more energy available and is more dangerous than

the ignition coil. Be forewarned.

As for a tesla coil, the original one was a sparkgap transmitter in the VLF - Middle frequency range. Details on building one are probably available in 1940-s and 1950s electrical experimenter's books in the library. You.ll know when you've found a genuine article when the book details how to make the glass capacitors used to resonate the coil. Also, Popular Electronics routinely publishes tesla coil designs of somewhat more modest scope than the 1.5 MHZ transmitter suggested.

3059. Grid Dip meter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-16 00:00:00 UTC
From: jimbob@acpub.duke.edu
Message-ID: <3ubael$kuk@news.duke.edu>
Source record: 111725

I'm building a high stability frequency source for the physics lab
and I need to get various oscillators and amplifiers working. A long time ago,
I had a Heathkit "tunnel" dip meter and liked it a lot. It really saved me a lot
of bother because I didn't need to use things like network analyzers and
sampling scopes to do the simple things.

I don't have the old dip meter any more and am wondering if anybody
else has one they'd like to sell. It doesn't have to be the tunnel dipper, just
something small with all the coils for 1 MHz to 250 MHz or so.

3060. Docs/Schematic/Info on KLB-110DX RF (HF) amp wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-16 00:00:00 UTC
From: bad@taz.WPI.EDU
Message-ID: <3ubalb$5ta@bigboote.WPI.EDU>
Source record: 111726

Hi,

I have a KLB-110DX HF Amplifier that I acquired as part of a deal. The preamp, and possibly one of the power transistors are blown, and I want to replace these. I also want a schematic so that I can see what kind of filtering this amp has. My problem is, I have no docs/schematics or anything (I don't even know what company made this amp).

Here is the info I have:
Model #: KLB-110DX
Made in: Japan
Serial #: 562065

On the front, from left to right, there is:
1. Power meter (100W max)
2. RX (aka Preamp) on/off
3. Power level (low/high)
4. Mode (SSB/AM)
5. Power (on/off)

And on the back there is a switch for the attenuator, so I can drive with either 0.5-3W or 3-10W.

Inside there are two variable caps, to tune the amp to any part of the HF spectrum.

When I drive it with my CB converted to 10 Meter FM (5W output) I get about 50W out, and the preamp definitely doesn't work.

If anyone has ANY idea, who could have made this amp, PLEASE let me know!

Before I get flamed for asking about what might be a CB power amp, let me assure you that this amp is for my CB converted to 10FM.

Thanks for your pointers/help.

3061. MAKE TONS OF $$$,IT REALLY WORKS!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-16 00:00:00 UTC
From: Homer
Message-ID: <3ubhb0$du4@vodka.intele.net>
Source record: 111727

Subject: AN EASY WAY TO MAKE $100,000 IN 30DAYS OR LESS, LEGALLY!

$$$ FOR YOUR RECIPES $$$

Please do NOT change anything contained in this letter EXCEPT as directed!

EARN AS MUCH AS $100,000.00 OR MORE IN 30 DAYS, LEGALLY!

EARN MORE THAN EXTRA MONEY!!
YOU WILL BECOME FINANCIALLY INDEPENDENT!!

Here's how to do it.
IT WORKS EVERY TIME! Again don't change anything.

Follow these instructions exactly and you could make $100,000 in the next 30 days. This program REALLY works. It makes money for those who do it honestly! Take the time to read it COMPLETELY!

I know, ordinarily, we disregard these letters because they usually don't
work like they're supposed to, but this ONE is DIFFERENT!

Carl Simmonds used this legal program last year and made $82,360 in cash
the first time he used it. Needless to say, he quit his job immediately
paid off all debts in full, and started another mailing.

Believe me, this is an EASY opportunity. You can do this all on your computer,
by "JUST PRESSING A FEW BUTTONS". You will EASE YOUR FINANCIAL PRESSURES,
and begin to make GOOD things happen for you and your family. READ ON!

* * * * * * * INSTRUCTIONS * * * * * * *

1. Send $2.00 (cash only) inside a sheet of carbon paper or construction
paper, and send a self-addressed, stamped envelope to each of the DEALERS
(1 through 4) below for the recipes they offer.

2 Save this letter on disk. Remove the name, and recipe title that is in the number 1 position. Move the others up a space. Put your name,
address, and the name of your recipe in the number 4 position.

3 Post this file just as it appears (with your name, etc.) in 10 different
places on-line (newsgroups, forums, etc.). Do the postings between 6 a.m.
and 7 a.m. Friday, Saturday or Sunday to get the highest position and have
your posting read first. Ten postings should yield about 100 responses,
which
should then yield about $100,000.

4 **When the money begins coming to your HOME MAILBOX, put your recipe
in the provided SELF-ADDRESSED, STAMPED ENVELOPE - sit back, smile, and
know that you
NOW OWN AN HONEST AND EASY SMALL HOME-OPERATED BUSINESS! KNOW ALSO, THAT
YOU HAVE DONE SOMETHING SMART TO ACHIEVE FINANCIAL INDEPENDENCE!

* * * * * LOOK AT THESE FIGURES WITH ONLY A 15% RESPONSE! * * * * *

Step 1: Fifteen dealers mail at least 15 letters each with your name in
position #3 AND send you a request for a recipe and $2 each or $30.

Step 2: Two hundred and twenty five (225) dealers mail at least 15 letters with
your name in position #2 AND send you a request for a recipe and $2 each
or $450.

Step 3: Three thousand three hundred and seventy five (3,375) dealers mail
at least 15 letters with your name in position #1 AND send you a request
for a
recipe and $2 each or $6750.

Step 4: Fifty thousand six hundred and twenty five (50,625) dealers send
you
a request for a recipe and $2 each or $101,250.

TOTAL CASH RECEIVED (15% RESPONSE) $108,480.00
ELAPSED TIME: 30 days! Everyone responding immediately.
ADVANTAGE: $8 Initial investment.

Professional care has been taken to insure that this Marketing Plan does
NOT violate any laws! (Reference U.S. Code, Title 18: Section 1302, 1343,
and TITLE 39, Section 3005).

The key factor is that we are Mailing Merchandise...OUR TREASURED
RECIPES.

Be honest in every way. Be sure to keep accurate records of income
for Income Tax purposes.

GOOD FORTUNE TO YOU!

* * * * * * * * DEALERS LISTED * * * * * * * *

1. Dan McNally (Easy Dump Cake)
26 Cambria Street
Clearwater Beach, Fl 34630

2. G. Bart (Exotic Spaghetti Sauce)
160 NW 176 Street #407
Miami, Fl 33169

3. Jason Meyers (Awesome Oatmeal-Raisin Cookies)
1695 S. 100 E.
Orem, UT 84058

4. Don Anderson (Atomic Salsa)
P.O. Box 3907
Winchester, VA 22601

****
S. Finch -- I made $141,000 the last time I used this program. It
REALLY
WORKS!
****
J.S. Holliman -- I am a skeptical person by nature. But I knew
this program was different. Over a period of 1 1/2 months, I received
a total of $137,870 in the MAIL!
****
P.S. Why not try it yourself? Mathematically it is possible, but
ONLY IF EVERYONE PARTICIPATES! This system works for the BENEFIT OF
ALL, so remember to begin with your name in the #4 position, for
MAXIMUM
SALES and PROFITS! THIS IS EASY AND YOU GET LOTS OF MONEY!!

GOOD LUCK !!!!!

Great Gary! I just hope this guy lives in your neighborhood, not mine. Cuz the only lethal danger to him isn't going to be just high voltage.

Of course, MIL-C-3092 (if my memory is right about the number) still contains a test procedure
for determining the hermeticity of glass encapsulated crystals that says something like, "In a
darkened room, bring the energized terminal of a Tesla coil near the crystal and observe the
color of the gas discharge...." :-)

My lab at work is across the runway from an international airport. Imagine the fun I could have testing crystals this way.

Happy RFI

Wes

3063. Motorola RF xistors ???

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-16 00:00:00 UTC
From: hduff@humnet.westonia.com
Message-ID: <792027019601@humnet.westonia.com>

Does anyone know of a cross reference for Motorola house marked RF transistors ? Wondering if these are your usual MRF- transistors that Motorola stamps with house numbers for use in thier own radio equipment?

ie.. M4018 (removed from an RF deck of a VHF radio) = MRF???

M9583 (on an RF deck from a low-band Mitrek) = MRF???
M1102 " " = MRF???

I'd like to have an actual cross list to MRF for all of thier Mxxxx RF transistors if it is available. Anyone ?

Thanks..Hugh Duff VA3TO Toronto

Dear Mike,

Thanks so much for your reply. The full name of the mag. I quoted from
is called Amateur Television Quarterly. Their NEW address is:

Three (3) North Court Street
Crown Point, IN 46307
Voice (219) 662-6396
FAX (219) 662-6991

Henry B. Ruh KB9FO, Publisher

$18.00/year for four (4) issues.

Lots of good articles and ads for things you can't live without! ;}

BTW, The device I was inqiring about IS the one you described. I received phone call from Harold B. from your company last Friday (7-14). He was great to talk to, despite the fact that we played a few rounds of phone tag between CA and WI. He gave me a brief history of your company, your product line, and said he would be sending some info via snail mail. I really appreciated the way I was treated by your company, even after I told Harold that I might only want to buy one transistor. Good customer service seems to be more and more proportional to the amount of the order involved. I won't hesitate to let anyone know how well I was treated by you folks.

I am anxious to see the specs. on the 20093 transistor. If you have the time, my FAX number is (608) 356-4777. A cut sheet would suffice. Harold said he would be sending a catalog, etc.

Thanks again for the reply!!

BC> I assume you'd need a good multi-turn pot, and the pot would
BC> probably need to have good temperature stability, but could one's
BC> VCO be be as simple as that?
Bob-
I think you will need data from Mini-Circuits, before your question
can be answered.
"Good" temperature stability is relative to your needs. My first
thought is that VCO stability doesn't need to be extremely good if its
intended application is in a Phase Locked Loop. If you're trying to meet
a requirement for a mechanically and thermally stable, manually tuned VFO,
then this may not be the way to go.

>This would be to broadcast in Calgary, Canada.
>If anyone could help me it would be greatly appreciated.

Contact your DOC (Canadian equivalent of the US FCC) and ask for information on applying for a broadcast license. In the US, getting such a license is expensive and time consuming, as are meeting the technical and financial responsibility requirements, if you can get one at all. In some markets, there simply aren't any open broadcast channel assignments available. In those cases, your best bet is to attempt to purchase an existing broadcasting operation. You can then, assuming regulatory approval of the transfer, assume the license and facilities of the previous broadcaster.

In the US, you'd expect to pay between $100,000 and $5,000,000 or so depending on market size (more in the very top markets) and type of operation (FM stations generally command more than AM stations). I'm not familiar with the going rates in Canada, but they probably don't vary much from that for equivalent size markets and facilities.

Broadcasting in large markets is a cutthroat business. You can quickly lose your shirt if you aren't very astute. In some smaller markets, a broadcast facility can be a relaxed mom and pop operation, a low stress retirement business. Calgary is a fairly large city, I'd analyze the market very carefully before jumping in. A good business plan is going to be essential.

You really should be asking this question in one of the broadcasting groups. That way you'd get input from more professionals. Not too many on this group are associated with broadcasting. Amateurs aren't allowed to do that.

well, the obvious answer is a well located repeater. i had the same problem but was able to communicate a good 20 miles by using a good repeater. another option is to get yourself a well situated antenna, a 3 element beam perhaps mounted on the roof pointed at your house (if you're only going to talk to one other person, no sense putting a roter up there). there's also the option of an amplifier.

spearce@ccu1.auckland.ac.nz said " The cd4066B cmos switch
has a cut-off frequency of between 4 and 7 MHz (not sure
precisely). He then added that he was looking for a similar
device that would pass higher frequencies.

This is an error I've seen made before. The CD4066B might have
a low switching rate, but that does not mean that it cannot
switch much higher frequencies. It's rather like a relay; you
can only switch it so fast, but the relay contacts can carry
much higher frequencies. It depends on the way the relay is built.
Same with CMOS switches.

My Motorola CMOS data book from years ago right off says that
the 4066B can "transmit frequencies up to 65MHz @ 10vdc". This
isn't in the fine print of the tables, but in the list of features
right up front. Just like a relay, the circuitry being used
around the CMOS switch determines things like crosstalk and
how well the device will operate at higher frequencies.

I remember an article in Radio Electronics or Popular Electronics
from years ago that had a useful intro to this matter. I have it
somewhere around, but don't ask me to look for it. It had a table
of the various switches in the CD4xxx series, and the highest
frequency they were good for and such. I wish I could remember
the details. I know that the CD4066 is generally a better choice
than the CD4016, but there is one exception and I can't remember
what.

This old Motorola data book doesn't help much, since they don't
use constant values to compare the same specs between the two
devices. A different company's data book might give a better
view.

The 4016 and 4066 are the same thing logically; spst gates.
In the 4xxx series, there are more complicated switching mechanisms.
I seem to recall from that old article that some of the
more complicated devices have better frequency transmission
ratings, but I quick glance of one of the other ones shows no
difference.

Of course, if you want to use one of the other ones, it would
have to fit your application.

Get some data sheets and start comparing. Get a more recent one,
and perhaps something like a 74HC4066 (or how ever the number will
come out) has not only a better switching rate, but a better

transmission rate.

There are also CMOS switches from other companies, Siliconix
used to make some, that might be looked at for better results.

>anyone help pull me through? Thanks.
>Rick Crider KD4FXA Monroe NC

Ok, Rick, the Jacobs Ladder first. Get a plexiglass tube about 6 inches
in diameter and 3 or 4 feet long. Take a neon sign transformer and connect
its HV outputs to two metal rods arranged in a Vee inside the tube. Leave
a small gap, 1/4 to 1/2 inch, at the point of the Vee. Set the tube upright
with the narrow part of the Vee down. Shoot the juice to the neon sign
transformer and watch the arcs crawl up the tube.

DANGER, DANGER, Will Robinson! This thing can bite. Keep well clear.

Ok, next the Tesla Coil. This is nothing but a resonant step up
transformer with a very high winding ratio driven by a RF power
oscillator. Get another plexiglass tube and wind about 280 feet
of #30 enamel coated magnet wire on it. Do this neat, no scramble
winding. This is the secondary. Mount a small metal ball, or a spike,
on one end of the tube and connect one end of your coil to this.
Ground the other end. Now wind a bigger air core coil of about 8
turns of 1/2 inch copper tubing and mount it around the base of the
other coil. This is the primary.

The secondary should be self-resonant around 1.5 MHz or so. Check
it with a GDO. Now add oil filled HV capacitors in parallel with the
primary until it is resonant at the same frequency. Again, use the
GDO. Make a one turn loop of #12 insulated wire around the base of
the primary. This is the tickler coil.

Now take a 4-400A, 3-500, 813, 810, or whatever big power tube you
have handy and wire up a Hartley oscillator using the primary
as the tank and the tickler for feedback. Turn that sucker on and
stand back. You should be able to draw arcs several feet long.

DANGER, DANGER, Will Robinson! This thing can bite *really* bad.

Note: both of these things will be RFI generators without peer.
You're going to wreck radio and TV reception for blocks around
when they are running. Both of these things use *LETHAL* voltages,
have a care. You or your cat could wind up dead.

Gary

3073. faster than cd4066b

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-16 00:00:00 UTC
From: spearce@ccu1.auckland.ac.nz
Message-ID: <3ub6if$2kl3@thebes.waikato.ac.nz>
Source record: 111871

The cd4066b cmos switch has a cut off frequency of between 4 and 7 MHz
(not sure precisely).

Are there similar or equivalent devices which are capable of passing higher frequencies?

Is so what are they called/how much do they cost/who makes them etc.

Many thanks

Stephen Pearce

The principal difference between the 4016 and 4066 is on resistance.
The 4016 is 300 ohms.
The 4066 is 75 ohms.

Circuit layout is critical at higher frequencies and cross-talk is a
major concern.

Any kind of outside or window mount antenna will probably do. I cary a handy talkie with a mag mount and a 30" Dimond/Comet dual band antenna for the rental car and then put it on the heater/cooler or refridgerator in the room. Use of a handy talkie amplifier (RF comcepts type) and a mag mount antenna should do the trick. If one or both rooms face one another and have some elevation ... high rise hotel. You should be able to work with handies and rubber ducks.

The 74hc4066 is rated at higher frequency but lower voltages.

There are a ton of different analog switches. "The Art of Electronics" by
Horowitz and Hill has a great writeup on them.

Try Maxim for some high speed video stuff. Other mfgrs. are Harris,
Analog Devices, and whatever they call Siliconix these days.

Hi,
Well *reliable* comms on UHF over this kind of a path is a dicey
proposition. have you considered buying/renting a couple of cellphones
(assuming of course the area has cell coverage)?
I worked in the 2 way business for 20 years here in the Minneapolis
area, and had many customers wanting this kind of coverage with
portables, but never had much luck even on a well based repeater system.
Mobiles and base stations are a different matter....
Good luck.

I said =LONG WAVE= *NOT* SHORT WAVE!
~~~~~~~~~ ~~~~~~~~~~

Long wave will not hurt your eyes. Short wave *WILL BLIND YOU*, and
that is what ARC welding generates. If you had read an earlier message
that I left a couple of weeks ago I left a very strong warning about
eye contact with short wave UV, as did many others.

KR>excessive exposure, "called arc eyes", does not appear until several
>hours after exposure. Its a feeling that someone has poured a hand full
>of sand in you eyes, and the rubbing only makes thing worse. Just like
>a sunburn... the retina gets blisters on it. Maybe... after two days
>you can recover... maybe just partly. You want to try it ?

Of course not, and we've all said that already. Short wave UV is what
is used to erase EPROMS and is BAD NEWS for the eyes. Somebody
mentioned using LONG WAVE to erase Eproms and I was explaining that it
won't work and mentioned you could look at long wave UV without eye
damage. You can buy long wave UV ("Black Light") tubes in many places,
and they are not shielded in any way as you want the "black light" to
flood the room to make your posters (or whatever) glow. K0ol man!

3094. Electrolytics

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-18 00:00:00 UTC
From: w9sz@prairienet.org
Message-ID: <3uf7gk$pv2@vixen.cso.uiuc.edu>
Source record: 111753
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew

Can anyone point me in the direction of a textbook which contains information on the design of electrolytic capacitors?

I am looking for information including what materials are used for the electrolytes, how to compute the capacitance, breakdown voltage, loss, etc.

I can be e-mailed directly on this. No need to burden the whole newsgroup!

73, Zack W9SZ

3095. SHF Microwave still there?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-18 00:00:00 UTC
From: smchenry@freenet.columbus.oh.us
Message-ID: <3ug6u9$27d@acme.freenet.columbus.oh.us>
Source record: 111754

Is the company SHF Microwave still in business? I ordered a 10GHz
Gunplexer type device from them some time a go and am now looking to order
another one. Also, all you folks who keep buying those "Brake light
testers", Put them to a REAL use and get on 10GHz so we have someone to
talk to. You wouldn't believe how easy it is.
Look in the back of the latest handbooks for very simple plans...
Please reply here or e-mail me at the address below. Thanks, Sean.
Also, looking for 10GHz WBFM skeds in the central Ohio area. KB8JNE.

>>
>>The 4016 and 4066 are the same thing logically; spst gates.

>The principal difference between the 4016 and 4066 is on resistance.
>The 4016 is 300 ohms.
>The 4066 is 75 ohms.

There is also the 74HC4066. 3 dB loss is 100 MHz @ 4.5v, 120 MHz @ 9v supply.
The main advantage is a lower "on" resistance of about 30 ohm.

There are also 74HC4051s (like a single pole, 8 position switch). I have often
wondered how they would work as an RF router in the front end of a receiver.
It would be nice to use a pair of these to select between up to 8 different
front end band pass filters rather than use a large switch.

Source record: 111759

To the group:

I have a pair of Eimac 4-400As that I think are in good
condition...envelopes look fairly clean, so probably not too many hours.
I have air-system sockets, chimneys and plate caps. I had planned on
using these in an HF amp, but due to time and monetary constraints, as
well as increasing difficulty in obtaining some critical parts, I have
decided to sell them. I would prefer to sell the parts as a group rather
than piecemeal. I would like $275.00 for the lot, but I would entertain
a very reasonable offer.

Rich,
WW0Q

3101. help needed with 2m channelizer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-18 00:00:00 UTC
From: ed@fore.com
Message-ID: <3uh3an$1tj@baleen.fore.com>
Source record: 111760

From Ed@fore.com

I have a GLB electronics channelizer model 400B that I want to
use with an ICOM ic21a. I dont have any info on the unit other
than my own measurments.

Tx freq output 6.?? mhz
Rx freq output 48.?? mhz

My Icom wants osc xtals around 18 mhz I think.

Unit internally oscillates around 24 mhz square waves from VCO.

The 24mhz gets divided down to 12mhz then again to 6 mhz then LC filtered
for the output for the tx freq.

The Rx is a different bird, it goes through a 74h00 (and gate I think?)
and is just buffered, then to a tuned circuit, that is tuned at about
48 mhz.

Any Ideas? Sources on info on this unit would be appreciated.
A schematic and users manual would be fantastic!

Please Reply Email Ed@fore.com

Hello Roman. You can get xtls on 10.106 from the following address:

Kanga Products, Seaview House, Crete Road East, Folkestone CT18 7EG

The price is 4 plus postage.
They also stock crystals on the other QRP freq's.
You might like to subscribe to the two newsgroups for qrp'ers, if you
don't already. Will send info if you need it.

so a question or two... first - what kind of ballpark ($$$) does 10Ghz
play in? Could a guy get active for a couple of hundred bucks?

second - what's the most painless way to start
learning it - assuming that I haven't had to pay much attention to much
theory in a good few years?

I've always been curious about Ghz-land but never moved above HF before -
and not much of that in the last few years...

Message-ID: <3ufi6d$ctv@idefix.eunet.fi>
Source record: 111767

Hi.

What makes you to feel that you have to replace the tubes, have you measured the output and foud the tubes "soft". How soft? Measure filament voltage also, some tubes are very sensitive to too low voltage (measure it when full load is on).

My suggestion is to buy 811's, cheapest ones because I think that they are good enoug.

(my exprience is that we need a full 100 % nut person to blow up a tube ... usually the tubes live very long, Very = 10-.20 years in proper amateur use)

The aforementioned SHF Microwave Parts had some really nice 10 GHz units
for $25. I got one that puts out about 10 mW.
Depending on how deep your junkbox is, the rest of the circuitry to make
a transceiver out of it could cost from nothing to $25-50, I think. (Far
under $100 for the whole project!)

You can actually get on the band with a Gunnplexer and an old FM radio or
2 meter rig, and an audio amp of some kind to modulate the Gunnplexer,
and a power supply or battery. See the ARRL Handbook from the late 80's.
You would actually need a friend on the band with a similar setup too;
it's nice to have someone to talk to!

I will send a request for a current price list to the address I have for
SHF and see what happens.

I have been attempting to repair an old Henry Radio Tempo 2020. A couple of the gears that drive the various bandswitches are cracked, split, or otherwise buggered up and need replacing. I have looked for them without success in two catalogs, Stock Drive Products, and Small Parts Inc. I also haven't been able to find them in any hobby shops either. Stock drive has some parts that are close, but not close enough. Any Ideas?

The gears have an OD of about 7/8", a pitch diameter of about 5/8" and 13 teeth. The bore contains a brass insert and a diameter of 1/4".

TITLE: yagiu109.zip

PURPOSE: To analyse performance of Yagi-Uda antennas. You
give the dimensions and positions of each element, and the
program calculates gain, input impedance, front-to back ratio,
beam-patterns etc. An optimisation program 'optimise' tries to
optimise a design. The optimiser can also tell you the sensitivity
of a good design, to small mechanical errors.

From: ptracy@aol.com
Message-ID: <3uj71a$aqt@newsbf02.news.aol.com>
Source record: 111780

I am looking for reccomendations for relays for T/R switching for VHF & UHF amplifiers. The next project is a homebrew "brick" for 223 MHz, and I already have the transistors picked out, and a board layout is currently underway. PIN diodes have been considered for T/R switching, but I just don't feel the added circuitry and biasing doo-doo is worth the effort. A relay's simplicity and relialbility seems hard to beat. The target output power is somewhere around 200 watts or so.

Hi.

Just had a mod done to my Cobra 148GTL. I've got lowers down to 26.81khz and uppers to 28.04khz. Cool deal!

My question is: Does a *mod* exist to allow transmission and receive from a VHF Marine Radio on 11 meters?? It seems like there should be because the 148 goes into 10 meters a little and started out as an 11M radio. The VHF is a 10M radio that would need to operate on 11M. The 25 watt supply found in the VHF would be nice on 11M.

Am I radically off base? I know a little knowledge is dangerous... but no worries because in this arena I don't even have that much :-)

Thanks
Wal

>this rig??

Any GE/Ericsson dealer should be able to order you a service manual for
this radio. It does make an excellent packet radio for 1200 baud. Because
it is phase modulated, you have to do some mods to make it work at 9600
baud. Basically, convert it to FM modulation by varactor modulating the
channel icom directly. You can do that and not lose temperature compensation
by using an opamp summer to combine the modulation with the temperature
compensation voltage. The IF filter is a bit narrow, however, and you
may have problems on receive. You can broaden it with a gimmick capacitor
across the narrower filter. However, a Motorola Micor is simpler to get
on 9600.

I am pleased to announce Positive Time System's new radio / power controller called the RCS-I. The RCS-I connects to any VHF/UHF radio and can send X-10 commands throughout your home or building. X-10 modules control AC appliances of any type and have been around for over 10 years through Radio Shack, Sears, Leviton and others. The RCS-I has other features like an alarm input that will page you, a listen mode to hear whats going on in your shack, a brief voicemail message, and many others. The RCS-I responds to all commands in a plesant female voice, and you voice for the call sign. More details are avaiable on the PTS homepage at:

http://www.halcyon.com/pos.time.sys/top

Mike,

Thanks so much for your reply. The full name of the mag. I quoted from
is called Amateur Television Quarterly. Their NEW address is:

Three (3) North Court Street
Crown Point, IN 46307
Voice (219) 662-6396
FAX (219) 662-6991

Henry B. Ruh KB9FO, Publisher

$18.00/year for four (4) issues.

Lots of good articles and ads for things you can't live without! ;}

BTW, The device I was inqiring about IS the one you described. I received phone call from Harold B. from your company last Friday (7-14). He was great to talk to, despite the fact that we played a few rounds of phone tag between CA and WI. He gave me a brief history of your company, your product line, and said he would be sending some info via snail mail. I really appreciated the way I was treated by your company, even after I told Harold that I might only want to buy one transistor. Good customer service seems to be more and more proportional to the amount of the order involved. I won't hesitate to let anyone know how well I was treated by you folks.

I am anxious to see the specs. on the 20093 transistor. If you have the time, my FAX number is (608) 356-4777. A cut sheet would suffice. Harold said he would be sending a catalog, etc.

Thanks again for the reply!!

73,

Bill KA9QFJ

3130. UK Repeater logic info Reqd.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-20 00:00:00 UTC
From: wilson_jo@grpr21.dnet.bp.com
Message-ID: <1995Jul20.040652.2053@rcwusr.bp.com>
Source record: 111789
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I've recently taken over as repeater keeper of GB3OH, the 70cm repeated located in East Central
Scotland.

The box seems to be working OK, apart from one small problem (and in dire need of a tune-up!).

As part of a club project for a group within the Falkirk Amateur Radio Club, we're intending to get
this repeater back on the air soon, but we lack any information on the system. The TX and RX
sections aren't too much of a problem, but we'd like to get some info on the logic.

It's discrete logic (no processor), and as far as we can tell, of a 1979 vintage. I know the logic
is a copy of some used somewhere in England, so it's not unique to 'OH, although it is possible
the original constructors of 'OH (now slient key) did modify it slightly.

The logic board is about 9 inches square, with a large PCB edge connector to the rear. There are
several presets located up the left hand edge of the board. By trial and error, we've determined
some of the functions of these presets, but we're still trying to figure out the others.

Does anyone have diagrams or any information on something this old? If you have, please email me here, or wilson_jo@grpr21.dnet.bp.com.

In the long term, we're hoping to revame the whole system, but as it seems to be working quite
well just now, we intend to get the box back on the air as it is.

A date for your diaries: 8th October 1995, from 11:00 to 16:30, the Falkirk Amateur Radio Club
will be holding a junk sale in the Scout hall in Grangemouth. Morse tests will be available.
Some of the proceeds of this sale will go towards the upgrading of GB3OH. Further details from myself at the above address.

John.

3132. [?] TV -> Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-20 00:00:00 UTC
From: rdc@freenet.vancouver.bc.ca
Message-ID: <3ul5is$ar2@freenet.vancouver.bc.ca>
Source record: 111791
Cross-posted to: rec.radio.noncomm,rec.radio.amateur.homebrew,rec.radio.scanner,rec.radio.amateur.equipment

Does anyone have any knowledge of converting an old TV to a (lousy?)
Spectrum Analyzer ?

My idea is to hook the vertical yoke to the speaker and the horizontal
ramp voltage to the tuner (with a pot or voltage divider between them for
some control).

With a marker I should just be able to change channels to move around the
spectrum and get a 'picture' of it. TV's have decent freq. range also ...
Not a Tektronix $100,000 setup but I should 'see' 'something'.

B/W TV's are cheap enough that I'm willing to butcher one ...
It would be helpful if anyone had tried this before or better yet knew of
an obtainable article on doing this...

Any tips would be appreciated or have I missed some intricacies of
television design that would prevent this from being possible ?

Don't laugh too hard as I only intend to cut a couple of wires and it
should be easy to restore it if need be ;>

3133. HP3047 phase noise software wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-20 00:00:00 UTC
From: jks@pajarito.sw.Central.Sun.COM
Message-ID: <3umhgk$1v3@handler.Eng.Sun.COM>
Source record: 111792
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I've acquired the phase noise interface (HP35601) from an old 3047 phase noise measuring system, but a complete system requires the 3582 and 3585 spectrum analyzers and a 9845T calculator (!) running special software. I'd like to hack the 35601 to work with my 4396 analyzer running IBASIC, so a few questions crop up:

Anyone have the 3047 measurement software? (tape cartridge for 9845T) Anyone know if it's distributed as source code (probably BASIC) or just binary?

If binary, does anyone have a pointer to the group inside HP that wrote the code? (probably early 80's)

If source, is the tape format compatible with anything modern or will I have to find a 9845T (ugh) to read it?

Ditto the above for anyone running the modern 3048 system.

It sure would be nice to measure down to -170 dBc/Hz @ 10 Khz for a change..

3134. WANT SILICON SYSTEMS SSI-202 DTMF DECODER CHIPS

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-20 00:00:00 UTC
From: mallorys@nbnet.nb.ca
Message-ID: <950720224358.85BD16@news.nbnet.nb.ca>
Source record: 111793
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Hello and thanks for reading this posting. I am in the process of building a repeater controller and a link controller. Both of these controllers need to have remote acess to the repeaters so that I will be able to shujt the system down and/or controll links as needed. Of course this will be done with DTMF tones, and to do this I need several DTMF decoder chips. Silicon Systems makes a SSI-202 chip that will do the job very nicely. Now you say there are all kinds of suppliers of DTMF chips, but, the problem is that most of these new chips are all microprocessors, and not what I want. Here in lies the problem. Where can I get a supply of these chips. I would prefer to get them iun Canada, but if needed I would go to the U.S of A. Any help would be greatly appreciated not only by myself, but from the members of the TRI-County ARC in Moncton New Brunswick Canada.

Please send reply to mallorys@nbnet.nb.ca

From: calhoun@teleport.com
Message-ID: <3ul4km$2nd@linda.teleport.com>
Source record: 111794

Well, I tried to make my own beam antenna, but something is wrong and I�m hoping that someone here can help. I started with the plans from "The Radio Amateur Antenna Handbook" by William Orr and Stuart Cowan. It is a three element designed to work at 144mhz. The plans called for:
Reflector: 41.75 inches
Driven: 39.4 inches
Director: 37.5 inches
Spacing: 10 inches
using 1 inch aluminum tubing. Of course I didn't read the instructions carefully until I was done. I used 3/8 inch solid aluminum tubing instead. It doesn't work very well. I used a SWR meter and got a reading of approx. 3.5

Does anyone have any suggestions for me?
dave

btw, I mounted the driven elements one above the other. Please email replies to dtpdave@aol.com if possible. Thanks,
dave

Wal,

Your message is completely garbled. Before attempting any frequency
modification on any radio, you should inform you about the basics.
First try to understand the difference between VHF and 11m
and between kiloherz and megaherz.

Isn't the mixer rated DC-xxx freq. You can use these mixers as attenuators by controlling the DC current thru one port. I would not expect it to be a problem unless the current went way high.

>My idea is to hook the vertical yoke to the speaker and the horizontal
>ramp voltage to the tuner (with a pot or voltage divider between them for
>some control).

The tuner and the vert. scan coils cannot react fast enough to the horizontal scan ramp. (to display a nice peak you would need a signal band width of a few 100 KHz).

An alternative might be to scan vertically and use the hor. coil for yor deflection. The horizontal scan generator (+ HV generator) may need the presence of the scan coils as a load, so you may have to provide a second set of coils.

The speaker audio is not a good source of signal strength, better will be the AGC voltage. You will need a booster amp to feed the scan coils with it.

If you disable the horizontal or vertical scan on a TV you have to reduce the beam current quite a bit to prevent "burn-in".

Don't get worried by folks saying that there are lethal voltages within TV sets. As long as you know what you are doing, you are perfectly allright.

From: Webbat1@cf.ac.uk
Message-ID: <3ukgr4$m0l@news.cict.fr>
Source record: 111803

I am working on a project which involves mounting independent electronic sensors under the skin to monitor various body conditions. The sensor(s) are powered from a small coil, which picks up a current from a transmitter outside the skin.

I am at present designing a transmitter for this. So far I have based my exciter around a 2N3819 FET and my power stage around some low power silicon bipolar devices.

These designes are not proving successfull, however. I hope that someone can send me some ideas and hopefully even some circuit diagrams, as I have been designing the exciter and power stages from memory, and I think I may have missed out some bits from the circuits.

Thanks in advance,
Andrew Webb, GERME

These's a PD program FDS (Fildes) that can give you the L and C values for filters.
It dont tell you how to wind then though.

3149. HP3047 phase noise software wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-20 00:00:00 UTC
From: jks@pajarito.sw.Central.Sun.COM
Message-ID: <3umhs2$214@handler.Eng.Sun.COM>
Source record: 111808

I've acquired the phase noise interface (HP35601) from an old 3047 phase noise measuring system, but a complete system requires the 3582 and 3585 spectrum analyzers and a 9845T calculator (!) running special software. I'd like to hack the 35601 to work with my 4396 analyzer running IBASIC, so a few questions crop up:

Anyone have the 3047 measurement software? (tape cartridge for 9845T) Anyone know if it's distributed as source code (probably BASIC) or just binary?

If binary, does anyone have a pointer to the group inside HP that wrote the code? (probably early 80's)

If source, is the tape format compatible with anything modern or will I have to find a 9845T (ugh) to read it?

Ditto the above for anyone running the modern 3048 system.

It sure would be nice to measure down to -170 dBc/Hz @ 10 Khz for a change..

We used to have a old 3047 system collecting dust and tried to get
it running again. Basically, it wasn't worth it. We ended up getting
a 3048 system, which is usable for some types of measurements, but
also has many, many limitations. And this was for use at HP (albeit
a different division than the one that made the 3047,8). I am going
to replace my 3048 with the cross-correlation system made by Femtosecond
Systems. It can go down to -190 dBc./Hz. Femtosecond is a company
started by Fred Wall's son, I think it's in Boulder, CO. Fred Wall
is the dean of phase noise experts at NIST in Boulder.

If you simply must obtain 3047 software, the keeper of that flame is
Bob Temple at the HP Spokane Division. He will probably not be too
happy if you ask him for ancient software, but he is the guy who
wrote it (along with a forgotten software man).

3154. Postscript files Help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-21 00:00:00 UTC
From: vinyn1vc@aol.com
Message-ID: <3uoean$q05@newsbf02.news.aol.com>
Source record: 111812

The ARRL BBS and FTP sites post various files in postscript files so that someone with the freeware program Ghost can easily print out a PC Board a laserjet printer. Zack Lau, KH6CP, has files available for his 10GHZ building blocks. Another neat program called HDL_ANT, written by N1BWT, will lay out templates for horn design and horn feeds for various parabola's, etc.
I have looked high and low for this Ghost program and finally found it on Compuserve. After downloading it and finding it do be about 700K, I fiddled with it for about a week. The documentation assumes you have used this program before and are a UNIX EXPERT! I do not fit either case. After about a week, I can print the circuits, but get errors on the fonts. So I commented them out from the .PS file, because it is not clear how to load them.

My other dillema, is that I don't have a postscript printer. I have access only to an HP Laserjet. Is there a way to make the conversion.

If anyone has a simple solution to the above I will be all ears. Is there a comercial package available to moreless plug in and go. The money may be worth the tradeoff for all of the time I devoted to this and still have not found a way to do make a usable printout. Thanks beforehand.

isn't there a software mixer control you can use to set the volume?
(however, running an SB 16 from OS/2 means i can go "behind" to use the
os/2 mixer to set the volume there when needed...so i don't know if there's a
lack of a volume setup for dos...)

the purely hardware solution would be to put an L-pad in the line between the
sound board and the speakers -- available at radio shack and many other
parts suppliers around the world...probably could get the right kind of cables
(jack to bare wire) to avoid having to assemble a connector -- will need a
box to put the control in tho...

>higher. Is this true??? Are they compatible??? Any prices???

First, although the 812A is similar to the 811A, it does *not* provide higher output. Plate dissipation is identical, but while the 811A has a MU of 160, the 812A is rated at only 29. Also, for a given class of operation, the 812A requires considerably more grid bias and is not well-suited for zero bias use. Finally, the 812A has a lower grid current rating than the 811A and may not hold up as well in Amateur service.

Regarding various versions of the 811A, you may be limited to using certain types, depending on the mechanical configuration of your amplifier. I haven't purchased new 811A's in several years, so some things may have changed. However, as of five years ago, amplifiers that mounted the tubes horizontally could not use the imports. While U.S. tubes had always specified a certain relationship between the orientation of the base relative to internal construction, this wasn't true of imported versions. As a result, the imports would eventually short internally due to element sag when mounted in amplifiers such as the Collins 30L-1.

I suggest that you contact one of the companies that supplies the various versions and ask their opinion. Personally, now that U.S. tubes are available again, I wouldn't consider anything else. The savings to be had buying impoprts is slight and may not justify the time and expense of dealing with an inferior product.

3161. Re: [?] TV -> Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-21 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <a3b_9507212230@mba.mba.org>
Source record: 111819

I haven't seen the original post, but apparently someone wanted
to turn an old tv set into a "spectrum analyzer".

From a snippet I saw in another post, I think the idea was to
simply leave the rf/if part of the set the same, and rearrange
the video circuitry to use it as what amounts as a big scope.

I was going to say that this wouldn't work because TV sets have
an if bandwidth of about 6 MHz or so, which is ridiculously large
for a spectrum analyzer. YOu might be able to detect the density
of signals due to combined signal strength, but it wouldn't really
tell you much about the individual signals.

Then it hit me that you wanted to use the audio output as the
vertical signal to the video section. At least that has an if
bandwidth of about 100KHz or so. Okay for fast scanning and getting
a broad view of the spectrum, though not useful for close up operation.

But there are two things wrong with this. Here in North American
(I don't know where the original poster was from, and I can't recall
if it's different elsewhere), the audio of a television signal is
an FM subcarrier. That means the detector is reacting to FM. For a
spectrum analyzer, you want the amplitude of the signals. If you've
looked at any of the "spectrum analyzers" described in the ham mags
in recent years (the ones using tv tuners for their front ends), they
do tend to use FM circuitry in the IF. But that's there so you can
listen to what's being transmitted, and a lot of VHF spectrum is FM.
But if you look closely, all of those analyzers tap off somewhere else
to get a detected amplitude to feed the vertical deflection of the
display.

The second problem is that it is a subcarrier. Traditionally, (and
I've seen articles about improving things so maybe in recent tv sets
things are done differently) the video signal is detected, and then the
FM detector is fed from the video detector. I remember reading somehing
in QST years and years ago about a correction to a short piece about
converting a tv set to a VHF receiver. Back in the tube days. The
correction was that without the video signal, there would be no signal
to feed into the FM detector. The solution was to convert the video
detector (the usual am diode detector) into a mixer, and add a
beat oscillator to mix the IF (in the 21 MHz range in really really old
tv sets, slightly above 45 MHz in everything since) to the 4.5 MHz
that the FM detector is set up at.

So not only is the FM detector the wrong choice, it won't even work
at detecting FM signals in this case.

ALl that being said, someone once did describe turning a tv set into
a band scanner. He took an old tv set, left the power supply and
some of the video circuitry in place, but ripped out the rf/if.
He basically used the tv set (and I think he did some mods on]
the deflection circuitry) as a wide screen oscilliscope, which worked
in this case since it was a limited application.

Then he added IF and multiple front ends (one for each of the
HF bands at the time). The front ends were varactor tuned. IN
the circuit somewhere was a switching mechanism that would switch
from band to band. So on the screen you would have each band
displayed at the same time, each above the other.

It was a great idea. There have been band scanners described, but
they all were limited to one band at a time, often using a tap
on the station receiver to get an IF signal. This one gave you
a very broad picture. But by doing it band by band, the display
was not cluttered up with the stuff in between bands, which was
not what you wanted for this application.

This article still might be useful, to see what the guy did to
the video circuitry of the tv set. You'd still have to basically
build the whole rest of the analyzer, but some of the circuits
I've seen are fairly simple (though their operation of course
matches). Find a tv set with a voltage tuneable tuner, find one
using ceramic filters in the FM IF, and combine them and you've
got it.

The article was in Ham Radio magazine, back in 1972. Maybe
sometime early in 1973, but I don't think so. IN the same issue
there's an early synthezier by ALfred Helfrick. But I don't
recall which month. The article was the cover article.

I hope this helps.
Michael

The relationship between gain and aperture area has nothing to do with additive gain vs. subtractive gain, supergain, etc. Perhaps what you really mean is physical volume, which is only very vaguely related to aperture area (large aperture tends to require large physical size, but there are many exceptions to this generalization).

Without supergain, you can't get an array gain of better than N using an N element antenna, no matter what the boom length, etc. For Yagis, supergain is basically confined to 2 and 3 element designs for practical reasons. For long Yagi's, you must have both enough elements and a long enough boom (near quarter wave spacing) to get maximum gain.

I have a large quantity of the Teltone M956 (22 pin IC). It is exactly
the same as the SSI-201 except that the M956 operates on 5 volts. The
chip uses a 3.58 Mhz xtal. I use the chip as a repeater controller and
touchtone decoder. It is commercial quality. You can have as many as
you need. The price is $22.95ea.

I have never heard of "Ghost", I do know of a program called "ghostscript"
that will convert postscript files to rasters that can be printed on dumb
printers or displayed on the screen. ghostscript is available through the
"GNU" free software foundation, I believe.

>
> My other dillema, is that I don't have a postscript printer. I have access

>

As I said above, you could print to a laser jet using ghostscript, but I have
never done so and don't know the details.

You might consider looking
around for a used postscript printer. A friend of mine picked up one at
a flea market for next nothing a few week ago. Be sure it has a centronics
port if you are using an IBM-compatible PC. If you are using a Mac or a
UNIX box any postscript printer should work. To test a used postscript
printers: on power up it should print a "start-up" page that tells you
the printer configuration, and proves the printer works. However, this
feature can be disabled by setting on a dip switch on the "back panel"
of the printer. Hopefully the seller knows about this. Also, there has to
be paper in the paper try, of course.

Once you have your printer, you need a driver. Sigh...

Another possible solution: I think you can purchase a postscript cartridge
for later model laser jet printers that allow them to interpret postscript.

> If anyone has a simple solution to the above I will be all ears. Is there
> a comercial package available to moreless plug in and go?

1. Buy an all new system (printer, computer etc) and have them configure it
at the store

2. If you have a Mac things are fairly simple. Mac's include postscript
printer drivers as part of the OS. But you still might software version
problems if you by the Mac and the printer separately and used.

In <3uoean$q05@newsbf02.news.aol.com>, vinyn1vc@aol.com (VINY N1VC) writes:
>I have looked high and low for this Ghost program and finally found it on

the program is really called Ghostscript. i want to say it's one of the things
under the GNUware banner or something like that.

>Compuserve. After downloading it and finding it do be about 700K, I

you didn't get it all.

>fiddled with it for about a week. The documentation assumes you have used
>this program before and are a UNIX EXPERT! I do not fit either case.

such is the way of free programs -- GS is pretty good tho...i think
Don Lancaster has some stuff that real postscript handles that GS didn't
(but that was a revision or so ago).

>After about a week, I can print the circuits, but get errors on the fonts.

that's the part you're missing..you'll probably have to include the fonts into
the data load for the program or figure out how to link a font directory into
GS to tell it where to find what it's looking for.

>My other dillema, is that I don't have a postscript printer. I have access
>only to an HP Laserjet. Is there a way to make the conversion.

i can think of a couple ways to go here:

buy Adobe Acrobat Pro.

comes with a distiller to take PS to PDF.
PDF's can be read by free viewers available for
dos, windows|OS/2, unix, macintosh (www.adobe.com)
PDF's can be viewed/printed on a wide variety of printers
includes those w/o postscript support.

you didn't say what version laserjet you have, there have been a number
of postscript add ons for the HP/Canon engines over the years.
good chance one exists for yours - not cheap and performance
is only fair. you'll need to max out the memory on the printer
if i remember right.

the truly simple solution is to scrounge up a used postscript printer.
we found a DEC used equipment dealer that was selling old DEC
scriptprinters (LN03 type beasts) around $500..i think there's a
series of printers around $1k-$1500 new (we locked onto the
old beasties because we already had some...they may not be for
the faint of heart...i recall they're Ricoh print engines and those

are a pain to maintain (seperate toner, drum, etc.)

>If anyone has a simple solution to the above I will be all ears. Is there
>a comercial package available to moreless plug in and go. The money may be

Acrobat -- i think i got mine for around $250 or so (YMMV). see the details on the Adobe Web Page...(I did ask Bart Jahnke about putting the forms into Acrobat so the exam generator software forms kit would be able to make forms that look like the original...but i guess i'll have to make up some examples.)

>worth the tradeoff for all of the time I devoted to this and still have

I have been using Go-script for some years now on my DeskJet+.
It is a Postscript interpreter and I paid +- $200 for it.
Goscript works with all kinds of printers and puts out postscript
files just fine.

It will turn your HP Laserjet into a kind of psotscript printer.
I have a postscript printer too and am impressed with the speed
of the DeskJet GS combo. May even be faster than the Richo7000PS.

You may have to fiddle with setups to get the down-loaded files to
print OK, but.

>Does anyone have any pointers to information of the performance or
>tolerance of electronic components in a vacuum? I'm interested in the
>behavior of transistors, dip-packaged IC's, carbon-film resistors and
>different types of capacitors.

There are two main concerns with operating electronics in a vacuum,
outgassing of the package materials, and thermal cooling concerns.

Outgassing can be a serious problem, and is suspected for contaminating
AO-10's Mode L antenna transfer relay, and thus reducing the calculated
link performance by about 10-15 dB. Designs should avoid leaving exposed
surfaces that can be harmed by outgassing contamination, and components
should be selected based on the outgassing products they produce. Except
for actual thermal vacuum chamber testing, or using previously space
qualified components, there's no source of data on vacuum outgassing
of common electrical components.

Thermal problems are more generic. Normal components are designed to
be air cooled. Without air, their cooling has to be done solely by
conduction and ultimately by radiation. Things like resistors and
transistors have to be heatsinked to the spaceframe and/or derated to
allow for the less efficient cooling from lack of convection. This
is calculatable for any component.

A related problem for satellite systems is thermal cycling stress.
The mechanical component bonds have to be designed to allow for
differential expansion and contraction under the impact of repeated
thermal cycling. That calls for good mechanical design and careful
pairing of component materials.

Subject: AN EASY WAY TO MAKE $100,000 IN 30 DAYS OR LESS, LEGALLY!
From: anonymous <gggg@grt.net>
Date: 8 Jul 1995 20:19:49 GMT
Message-ID: <3tmp95$b4v@saba.info.ucla.edu>

$$$ FOR YOUR RECIPES $$$

Please do NOT change anything contained in this letter EXCEPT as directed!

EARN AS MUCH AS $100,000.00 OR MORE IN 30 DAYS, LEGALLY!

EARN MORE THAN EXTRA MONEY!!
YOU WILL BECOME FINANCIALLY INDEPENDENT!!

Here's how to do it.
IT WORKS EVERY TIME! Again don't change anything.

Follow these instructions exactly and you could make $100,000
in the next 30 days. This program REALLY works. It makes money
for those who do it honestly! Take the time to read it COMPLETELY!

I know, ordinarily, we disregard these letters because they usually don't
work like they're supposed to, but this ONE is DIFFERENT!

Carl Simmonds used this legal program last year and made $82,360 in cash
the first time he used it. Needless to say, he quit his job immediately
paid off all debts in full, and started another mailing.

Believe me, this is an EASY opportunity. You can do this all on your
computer,
by "JUST PRESSING A FEW BUTTONS". You will EASE YOUR FINANCIAL
PRESSURES,
and begin to make GOOD things happen for you and your family. READ ON!

* * * * * * * INSTRUCTIONS * * * * * * *

1. Send $2.00 (cash only) inside a sheet of carbon paper or construction
paper, and send a self-addressed, stamped envelope to each of the DEALERS
(1 through 4) below for the recipes they offer.

2 Save this letter on disk. Remove the name, and recipe title that
is in the number 1 position. Move the others up a space. Put your name,
address, and the name of your recipe in the number 4 position.

3 Post this file just as it appears (with your name, etc.) in 10
different
places on-line (newsgroups, forums, etc.). Do the postings between 6 a.m.
and 7 a.m. Friday, Saturday or Sunday to get the highest position and have

your posting read first. Ten postings should yield about 100 responses, which
should then yield about $100,000.

4 **When the money begins coming to your HOME MAILBOX, put your recipe in the provided SELF-ADDRESSED, STAMPED ENVELOPE - sit back, smile, and know that you
NOW OWN AN HONEST AND EASY SMALL HOME-OPERATED BUSINESS! KNOW ALSO, THAT YOU HAVE DONE SOMETHING SMART TO ACHIEVE FINANCIAL INDEPENDENCE!

* * * * * LOOK AT THESE FIGURES WITH ONLY A 15% RESPONSE! * * * * *

Step 1: Fifteen dealers mail at least 15 letters each with your name in position #3 AND send you a request for a recipe and $2 each or $30.

Step 2: Two hundred and twenty five (225) dealers mail at least 15 letters with
your name in position #2 AND send you a request for a recipe and $2 each or $450.

Step 3: Three thousand three hundred and seventy five (3,375) dealers mail
at least 15 letters with your name in position #1 AND send you a request for a
recipe and $2 each or $6750.

Step 4: Fifty thousand six hundred and twenty five (50,625) dealers send you
a request for a recipe and $2 each or $101,250.

TOTAL CASH RECEIVED (15% RESPONSE) $108,480.00
ELAPSED TIME: 30 days! Everyone responding immediately.
ADVANTAGE: $8 Initial investment.

Professional care has been taken to insure that this Marketing Plan does NOT violate any laws! (Reference U.S. Code, Title 18: Section 1302, 1343, and TITLE 39, Section 3005).

The key factor is that we are Mailing Merchandise...OUR TREASURED RECIPES.

Be honest in every way. Be sure to keep accurate records of income
for Income Tax purposes.

GOOD FORTUNE TO YOU!

* * * * * * * * DEALERS LISTED * * * * * * * *

1.
Dan McNally (Easy Dump Cake)
26 Cambria Street
Clearwater Beach, Fl 34630

2.
G. Bart (Exotic Spaghetti Sauce)
160 NW 176 Street #407

Miami, Fl 33169

3.
S.R. (Oatmeal-Pecan Cookies)
P.O. Box 411496
Los Angeles, CA 90041

4.
KLS
(Home Made Irish Soda Bread)
P.O. Box
Boca Raton, Fl

****

S. Finch -- I made $141,000 the last time I used this program. It REALLY WORKS!

****

J.S. Holliman -- I am a skeptical person by nature. But I knew this program was different. Over a period of 1 1/2 months, I received a total of $137,870 in the MAIL!

****

P.S. Why not try it yourself? Mathematically it is possible, but ONLY IF EVERYONE PARTICIPATES! This system works for the BENEFIT OF ALL, so remember to begin with your name in the #4 position, for MAXIMUM SALES and PROFITS! THIS IS EASY AND YOU GET LOTS OF MONEY!!

GOOD LUCK !!!!!

Hi All

Can anyone tell me if they have come up with anyway to modify
a TS120V to accept a transverter socket? Id much prefer this way rather
than start relay switching a high power attenuator in/out of the
transmit line.

Any info appreciated.

A rare golden bird - super condition!

Tektronix spectrum analyzer, composed of the following components:

- 7613 frame, selectable *storage scope* or normal trace
- 7A17 fixed gain amplifier plug-in
- 7L12 1.8 GHz spectrum analyzer dual-wide plug-in
- a spare 7603 frame, but display tube is non-functional

The left of three slide-ins is taken by a no-frills, fixed gain vertical amp. This is available as the left channel on the mainframe. The center and right slot are the spectrum analyzer, and show as the right channel on the display.

On screen dynamic range: 80 dB.

Sensitivity: picks up all the local TV and radio stations using a paperclip on the input connector. The sensitivity dial spins around to a minimum reference level of -100 dBm.

Tucker sells just the 7L12 plug-in for $3995, but street prices seem to check out at 1/2 to 1/3 of Tucker's. I offer the entire package for $1725, including the second mainframe for spare repair parts. I'm packing for a move on 14 August. E-mail back soon!

Plagurized from the July 95 issue of PRINTED CIRCUIT FABRICATION:

"Rewards Paid for Vintage Wattmeters

"'Quest 43' has been launched by Bird Electronic Corp (Cleveland, OH) to locate the oldest working Model 43 Thruline wattmeter. The search celebrates the company's recent production of the 250,000th Model 43. Winners will be announced at the International Wireless Communications Expo/Spring '96 Convention, to be held April 24-26, 1996, at the Las Vegas Convention Center.

"Rewards will be offered to owners of the 10 lowest serial number Model 43 wattmeters in working condition. The owner of the lowest serial number will receive a 24-KT gold-plated Model 43 and a $1,000 gift certificate to the company's catalog. The next nine lowest serial numbers will receive $250 to $500 gift certificates. All 10 owners will be sent a new wattmeter to replace their vintage unit.

"Entries must be received by January 31, 1996. All Model 43 owners seeking additional information or an entry form are encouraged to contact Greg Johns at (216)248-1200 ext 261."

The big problem here is one of cash - yes, we could replace the logic, and we'd very much like to, but new logic isn't cheap. If we take the cheaper route, and start to develop our own, that takes time. We have a working box, and we'd like to get it on the air, then start an upgrade program.

A complete answer will follow; until now i will just say: It is
possible! I already built a working device. There are some problems
involved (IF-Bandwidth, AGC,...).
- use vertical scan as tuning voltage
- compare the SSI voltage against horizontal scan voltage; if equal
activate video output

Help please,
I have a 900MHz power amp module, purchased new at a flemarket.
It looks like it bolts onto the back of a rig, as it has large heatsink
fins on one side.

It has the following printed on the PC board,

MULITPOINT NETWORKS
900MHz POWER AMPLIFIER
PC100033 Rev. 1/C

It has 2 RF connections, and an 8 pin header (next to a trim pot.)
Is anyone familiar with this module, especially the pinout of the
header?

I would be very grateful for any info on the unit.
Thanks for your time,

>plate transformer, 1 amp at 3000 volts...

Have you thought about junk microwave ovens? I used to service these years ago, customers used to junk these left & right, The parts are $$$!, 99% of the time the transformer was still good.

The average Tappan m/w oven had a secondary of about 1200v ac that could deliver 1a+ pretty much 100% duty cycle. You could get a couple of these and string them in series for the needed B+. You might be able to make a deal with a repair shop, 'I'll haul these heavy beasts away for free for you'... ?kw worth of transformers (wont be light weight) for some strong back work?

There are also doubler circuits, big caps, thickly insulated wire, interlock switches, hv diodes, relays/triacs...

Its an Idea, may not be the best idea, but its better than nothing.

Can anyone tell me the maximum gain one would expect of a Yagi of a known boom length?
Better still, whats the apeture area of a Yagi? I know a formulae relating max
gain (without supergain) to apeture area.

davek<<<<

Hi Dave, There are many published charts showing gain vs. boom length. I'm not sure how accurate they are since the ones I have seen are in Handbooks.

It is my understanding you are correct. The effective apature does relate directly to the gain of the array, and vice versa. That is the long and backwards way to estimate gain however. A direct measurement works best, and then the measured gain can be used to calculate the apature

Rewinding transformers from power poles will produce the cheapest high power xformers I know of. It might be a little more power than you need. A 100 amp house transformer should handle about 18 amps at 1200 v a pretty healthy safty factor.

Source record: 111715
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

----- Update from original poster -----
From the replies I've received this is 'where we are now':

A few repliers and myself have figured out we can use the VERTICAL scan (60Hz) ramp voltage to tune the TV tuner synchronously with the vertical position. By rotated the yoke 90' the picture could be 'right-sided' (and with some height/width adjustment the picture 're-sized') converting the display back to the 'normal' horizontal type.

Tapping the AGC and amplifying that (instead of 'the sound') will give a strength indication similar (but uglier) to a Spectrum Analyzer (I hope!).

Intended for use on 2 meters.

After testing on an old full-sized set I'd like to continue the idea with a hand-held (CRT, not LCD) portable from Radio Shack (so that interested parties can obtain the same set and follow the MOD instructions easily).

I expect to have the neccesary test equipment and an old TV ready next week.

3207. re: WANT SILICON SYSTEMS SSI-202 DTMF DECODER CHIPS

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-24 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <c43_9507241730@mba.mba.org>
Source record: 111716

mallorys@nbnet.nb.ca (Stephen Mallory) was looking for
a Silicon Systems SSI-202 DTMF decoder, and was hoping it
could be found in Canada. He is interested in this part
since it's meant for standalone operation, rather than
intended for use with a computer.

I don't know where to get them in Canada. Maybe Electrosonic
in Toronto, but I thought they had quite a high minimum order.

I don't have a recent catalog, but
Active Electronics
237 Hymus Boulevard
Pointe Claire, Quebec
H9R 5C7

1-800-363-7601

had a number of DTMF decoders in their catalog from a few
years ago. Minimum order is something like $25, though.
They have local stores across Canada, but I don't see anything
in the Maritimes.

I want to point out that the SSI-202 is not the only stand-alone
DTMF decoder. The 8870, I forget the prefix but it's made by
a couple of companies, is similar in circuit to the SSI-202. I
don't think the pinouts are the same, so be warned.

There have been articles on both these devices in both
Radio Electronics/Electronics Now and 73, for sure. I could
find the references with some effort. They have been about
ham use, by the way.

I was looking for some DTMF decoders for a project and was
put off by not finding a source that wouldn't require a minimum
order or all that trouble of ordering across the border. I ended
up finding some 8870's on some circuit boards at the local
surplus outlet. Too bad the project was no longer needed. I
saw the board, brought one home to puruse it, and by the time
I got back, somebody else had snapped the rest up. It was
some kind of telephone interface board. If you have any
surplus stores over there, you never know what might turn up.

I also ended up with some sort of telephone board for an IBM
compatible that not only had a DSP IC, but a tone decoder. Not
likely to get the thing going since it came with no manual
or software, but it is terribly intriguing. I got it in a box
of other computer boards at a garage sale, and I paid only a dollar

for the box.

I want to add one really important thing. Apparently your original post has brought on a deluge of posts by some guy with a bunch of DTMF decoders that he wants to unload. He wants $23.00 for them. I haven't done a lot of pricing, but that seems terribly high for DTMF decoders.

One place that sells both SSI-202 and 8870 DTMF decoders is
B.G. Micro
PO Box 280298
Dallas, Texas 75228
USA

214-271-5546

They've been around for years, though I've never order from them. An ad from them in Electronics Now last year had both the SSI-202 and 8870 Decoders, either kind for $2.25. They don't seem to have a minimum order, but they do have a minimum $7.50 shipping and handling fee to Canada. Kind of costly if you buy only one, but if you need a few more, it might be the best place.

It would seem a lot less costly than the guy trying to sell his here.

Someone else was asking about the IC's the guy was selling. Basically, both these DTMF decoders use minimum circuitry. A color subcarrier crystal (3.58 MHz), easily found in a color tv set lying on the sidewalk waiting for the garbage truck, a couple of resistors and capacitors. The output is a four bit data set, and a line that would indicate that the data is ready. There's a bit more, but that's basically it. The IC's do operate by themselves, but they can be easily interfaced to a computer. Feed the four data bits into a parallel input port, and use the strobe line to indicate that things are valid. It's really a matter of software than a hardware problem.

Hope this helps.

CQ anyone trying to build K7OWJ's "Continously Variable Bandwidth
Audio Filter" described in the July issue of QST.

I'm looking for insight in getting this puppy working.

Yes, I have seen the errata listed on page 79 in the August QST.
The only other change I've made is the use of the MAX297 instead
of the MAX295 (conveniently unavailable until October ;-)

I do have good clock output from U5, the 555 timer, in
the suggested frequency range (37kHz to 180kHz)

I'm wondering if the MAX297 is not a direct replacement as K7OWJ
suggests.

Thanks - KB7QPA

>boom length?

Hi Dave,
The formula (from that very good book, "The VHF/UHF DX book", DIR publishing,
Buckingham, England Ed Ian White G3SEK, page 7-16, go get a copy right now)
is
gain= 7.8log10(size in wavengths)+9 dbd

valid for 2-50lambda.

Your results are not too far out of the ballpark. Several issues can account for the difference. For one thing, most coil formulas are based on solenoidal coils where the length is several times greater than the coil diameter. If this assumption is violated than you will notice a difference.

The frequency at which the coil is used will also determine the final value of inductance. This is because the effects of stray capacitance and characteristics of the coil form are influenced by frequency. Some coil form materials are better than others. For example, nylon is not very good because it can absorb moisture from the air. Polystyrene is usually pretty good. Some ball point pens are made of polystyrene which can make a good coil form for the HF frequencies.

And of course you can always wind the coil for more inductance than needed and trim it to final value by removing turns. Increasing the number of turns by 40% doubles the inductance of a coil (the inductance is proportional to the square of the turns).

Also, don't overlook the fact that your L meter might not be properly calibrated. Measure one of your inductors with a quality calibrated L meter. Then save the inductor as a personal standard. A university physics or EE department lab should have a meter that is reasonably accurate. Note that many of the mass produced Taiwanese digital volt meters include an LCR meter, but don't rely on the calibration to be dead on. They are not laboratory instruments (but they are good enough for most ham radio construction projects).

3212. 2.5 mm stereo

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-25 00:00:00 UTC
From: jimlasal@telerama.lm.com
Message-ID: <3v3dsj$6ge@pink.lm.com>
Source record: 111625

Buck Rogers gives some tips for interfacing the Alinco DR-150T to packet in the July '95 issue of CQ magazine. He took time to point out that a 2.5 mm STEREO plug is difficult to find. He's right. I called Digi-Key and for the first time (at least for me) they were stumped. I'd rather not jury-rig the patch cord/adapter detailed in the article. Does anyone have a source for 2.5 MM stereo jack?

Tnx in advance.

Does anyone happen to know where to find a program that will allow you to specify the coil dia. , wire ga. and inductance and the program will give you number of turns? A ftp or www site would be great! I mainly want it for VHF/UHF frequencys.

You can post in newsgroup or email me at markman@UTM.Edu

Thanks in Advance!
Mark

3216. Re: [?] TV -> Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-25 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <ce3_9507251330@mba.mba.org>
Source record: 111629

rdc@freenet.vancouver.bc.ca (Robert Clark), who I believe
was the originator of this thread, made some coments about
the information he has received so far on the matter of
turning an old tv set into a "spectrum analyzer". After
making some reasonable comments about the deflection circuit,
he added:

"Tapping the AGC and amplifying that (instead of 'the sound') will give a strength
indication similar

to a spectrum analyzer (I hope!)."

I already made a comment about this, and I'm sure I implied
something about this point, but this is not going to work.

The bandwidth of a tv set is something like 6MHz wide. Bigger
than the whole 2M band. You won't be able to differentiate
between the individual signals, because there is no way that
they will stand out from each other.

The agc voltage that you want to use instead of the sound
(which is FM here in North AMerica), will be a reflection of
all the signals in that 6MHz or so band. It will more or
less reflect the density of signals in that 6MHz segment,
but it will not reflect individual signals.

To repeat what I said before, if you want to do this you
will have to convert the existing 41MHz IF signalof the tv
set down to a frequency where you can get better selectivity,
and pick of some sort of signal strength there.

The idea of using an old tv set for the display is not too
unreasonable, as long as your desired scan rate fits the
limitations of the set. Using the tuners is also a good
idea and has been done in numerous "spectrum analyzers"
described in the ham magazines over the past decade or so.
But I think you may be much better off junking what's between
the tuner and the display circuitry, and building a simple
double conversion IF strip that will have the needed selectivity.

3219. Do vacuum tubes have shelf life?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-25 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDCA70D.HFJ@netcom.com>
Source record: 111632

Like most good people in the world, I'm saving for my retirement.
That savings includes a pretty good pile of transmitting and receiving
tubes, some new, some used. For me retirement is still 20-30 years
away.

Will these tubes retain their vacuum if stored "properly"? I've heard
that tubes get gassy, and perhaps some of my used tubes are in this
condition but are still usable. Does the gassy characteristic get worse
with time, or with usage?

Thanks,

73 Dave WB0GAZ dgf@netcom.com

<blush !> Tnx Joe, your check is in the mail :-)

Actually the formula comes from DL6WU, and strictly speaking it
applies only to his own long yagi designs. It may be possible to
get a few tenths of a dB more - and of course there are many yagis
achieving much less!

Remember that gain isn't everything. Most designs that achieve
higher gain than the DL6WU are doing it at the expense of some
other aspect of performance, such as tolerance to manufacturing
variations, stacking and the detuning effects of raindrops.

Hi Thomas!

Thanks for your reply. I am using a digital LCRQ meter. It may not be as accurate as a lab. meter, however, it is probabley better than a DVM with LC functions.

I'm using bakelite tubes for my formers and I mount those on a modified hand-drill. This way I have made coils with resonably uniform and firm windings. The lengths of my coils are always longer than twice their diameter.

My real "problem" is not so much inaccuracy but the fact that the error is not constant. If I could find a relationship between inductance or physical dimensions and error then I could derive some for of correction factor and should then be able to "design" and wind the coils resonaby accurately.

However, the range of errors is quite wide and that's what's bugging me.

It is great fun though and I wont give up yet. I am getting better at it and now only use 3 sizes if the bakelite tubes so Im getting to "know" them.

thanks again for your reply, regards, ference

i guess i might suggest reviewing the ARRL Handbook and other books.
there was even an L/C slide rule calculator at one time (think i have one
buried around here). in any case, the formulas are pretty straight forward
and can be easily implemented in a spreadsheet, basic program or even
a programmable calculator.

of course at VHF/UHF the rules change a bit on just what's an L and a C and
exactly where those have to go to be those...

Gerald:

I can probably find other info given time, however, one article at hand is "An All Band 4CX1000A Super Cathode Diven Amplifier" in CQ MAgazine for April, 1970. This design did not cover six meters, though. I'm not sure 160 - 6 coverage is too practical either. I'm not saying it can't be done, I just think you're asking for heartburn.

If you want a copy of the article, please send your mail address.

It seems to me that I recently read something in QST (Technical Correspondence, I think) about
this topic. Of course, I have a habit of bringing out the old issues and going over them again, so it could have been in an older issue. The author developed some new equations for calculating inductance and pointed out the errors in the old "reliable" formulas.

Maybe Zack will read this and remember. Otherwise, say the word and I'll try to find it again.

Bill, how archaic -- to suggest actually reading a book. I thought we hams were past all that and had become "modern". After all, we no longer have to "dip the plate and peak the grid", why should we have to actually read and understand something? :-)

Hi Gerald,

The 4CX1000A should work well on six meters, but I am afraid you will run into network and choke problems on one end (160) or the other (6). It is almost impossible to get a good plate choke from 160 through ten, let alone trying to include six! Plus the stray capacitances and lead lengths will kill performance on six unless you are very very careful.

There is as much in-correct as correct advice in amateur publications on amplifiers. I would get a copy of Eimacs publication "The Care and Feeding of Power Grid tubes" and read it carefully. I would also avoid witchcraft and voo-doo circuits.

For the 4CX1000 I would recommend copying Collins 30S1 circuit. Screen regulation, control grid regulation, and current protection is absolutely necessary if you want a good clean long lasting amplifier.

The Collins circuit was "borrowed" and published as a "Super Cathode Driven" amplifier, but be aware the circuit ONLY WORKS with a class AB1 tetrode or pentode, it will NOT perform correctly with triodes of ANY class, or tubes that draw ANY amount of control grid current such as 4-1000A or 4-400A tubes.

Used correctly, the Collins circuit reduces chances of damaging the grid and improves linearity. Used in incorrect applications it lowers linearity,
stability, and gain flatness. NEVER use the "Super Cathode" circuit with ANY triode or in any amplifier that produces control grid current!!!!!!

A second method I use involves a non-inductive (be SURE it is really non-inductive) resistor from the grid to ground and normal screen and bias voltages and connections. The value of the control grid resistor for class AB1 using this grid swamping resistor is given by the bias voltage squared over two times the driver power. The screen grid MUST be grounded with a very low HF through VHF impedance connection or the tube will be unstable. If you ground the screen correctly there is usually

no need for any parasitic suppression device with this tube.

The 4-1000A is a generally unstable tube because of the long internal grid connections, but is also a much more rugged tube in terms of control grid problems. I would use the 4-1000 in conventional grounded grid with ALL grids tied directly to the chassis with VERY short heavy leads. You should use a special parasitic suppressor with this tube. It is

usually be a real pain to stabilize because it trys to oscillate at low VHF
frequencies.

I would use a parallel resonant parasitic supressor tuned to the 60 to 80 MHz range, or a series parallel circuit consisting of a series 100 ohm R and 115 nanohenry inductance, and a 27 picofarad capacitor placed across a 4 turn 1/2 inch diameter #10 copper coil at the anode terminal of the 4-1000A tube.

That will give complete supression without unwanted heat or performance degradation on 15 and ten meters.

Most conventional carbon and metal film resistors have considerable internal inductance that renders them useless as a suppressor resistor in most applications. Either cut a sample component open and look at it or measure it on an impedance bridge (the MFJ-259 works great for this). If the resistance element is wound in a spiral the thing is usless for suppression. As far as I know only Allen Bradly still makes non-inductive 2 watt carbons, I can source them if you have trouble. Even the small grey metal films are too inductive for some suppression applications.

Good luck with your project. 73 Tom W8JI

3237. Re: Do vacuum tubes have shelf life?

>>>Will these tubes retain their vacuum if stored "properly"? I've heard that tubes get gassy, and perhaps some of my used tubes are in this condition but are still usable. Does the gassy characteristic get worse with time, or with usage?

Thanks,

73 Dave WB0GAZ dgf@netcom.com<<<

Dave,
Seal leakage can contaminate the tube with age. This is a real problem with some transmitting tubes like 3-500Z's. The getter that absorbs gas is on the anode, and is activated by heat. If you let a metal anode 3-500Z sit for several months and apply HV (and perhaps RF) the thing will often let out a loud bang and kill some components.

The 3-500Z anode has to be turned red once in a while to de-gas the tube. Some other tubes have the getter on the heater or catiode structure. They will de-gas without HV just by applying filament power for several hours.

But like so many thing in life, it all depends on your luck. A friend of mine (K8KAS) went to Dayton with me one year. I bought used 3-500s from a guy and Denny bought new ones that were the same age but never used. He stuck them in his amp and POW! it arced over. I used the used tubes for several years! ;-)

Ceramic tubes are better on the shelf. I am not sure about small receiving tubes since I have no experience with them, but I suspect they are less of a problem since the seal area is smaller and the voltages lower.

Message-ID: <3v8mb8$m45@unisql.unisql.com>
Source record: 111651

Use an LM317 regulator IC. This gives you 1.7 to 37 volts at
up to 1.5 amps. Need more current out? Drive the base of a
2N3055 pass transistor with the output of the LM317 for 5 amps
and if that's not enough, feed the base of several paralleled
2N3055s with the emitter of the first 2N3055.

National Semi's Linear Databook has app notes on the LM317, as
does the Radio Shack semiconductor ref book. This is easy to build out of
surplus junk.

It should go without saying that you need a transformer and bridge
rectifier of adequate power-carrying capacity for your application,
as well as several thousand microfafads' worth of filter capacitors.
Protective circuitry is recommended as well.

Email me if you're still clueless or need a schematic.

Hi.
I writing my diploma thesis right now (it's about the theoretical
development of a PR network - protocols mainly)and I'll have to have a
section about the hardware as well. Unfortionately that's not my favorite
topic. :^(
The HW must be able to transmit digital data at, say, 1 to 10 MBit/s in a
range up to 5 to 10 km in urban areas (more in open terrain) using
omni-directional antennas.
I now thought, you tech-wizards would be able to tell me what the
transmitter/receiver schould look like, wich modulation I should
(theoretically ;^)) use and all such things wich must be considered.
Also I need pointers to widly available (scientific) litrature on these
questions, so I can give some references in my paper.

Please send answers as eMail or use the CC: field with follow-ups, 'cause
I'm on holiday for 3 weeks now, so I'll miss pure follow-ups.

Any help is really aprreciated!

Thanks, Kai

From: jkbe@zeus
Message-ID: <DCE3sE.M50@nntpa.cb.att.com>
Source record: 111655

Just in case others are interested....

The EPROM image for the CMOS Keyer in August QST is not available from ARRL or the author. Also, according to the author, the security bit is set in the microcontroller which would prevent anyone from duplicating the chip.

Does this bother other builders? I'm sure the ARRL frequents this newsgroup and would be interested in how you feel.

John

3247. Re: August QST CMOS Keyer 3

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-27 00:00:00 UTC
From: Jim Strohm <jstrohm@blazer>
Message-ID: <3v8vhs$oes@unisql.unisql.com>
Source record: 111656

Does it bother others that the software is copy-protected?

If I had written a _commercial_ program, I'd want it protected
from free use and from unauthorized modification, and I'd like
to get paid for it. This isn't inconsistent with commercially
available ham gear.

However, I feel it violates the spirit of experimentation and
"build-it-yourself" that ham radio used to be based on. Since
it's not a project I'd consider building, it doesn't affect me.
But if you're bent out of shape, it certainly is in your
interest to write the ARRL, the author, and the provider of the
programmed chip and express your feelings; and to urge others
to share their feelings. Maybe this would cause the ARRL not
to feature "read-only" firmware in construction projects.

Here's a thought -- my oldest ARRL handbook dates from the 1950s.
While many of the parts in those projects are available from one
source or another, most of the suppliers are long since out of business.
How would I be able to build this project in 20 years (if I choose to)
if the firmware's locked up and the company's out of business? Before
anybody says that's impossible that anyone would build a project from 1955,
take a look at how long we've been building 811A-based amps and then
look in the Ameritron catalog.

Is the range of errors you see on attempts to reproduce exactly the same coil, or on attempts to produce coils of different dimensions? If the coils are supposed to have the same dimensions but don't have the same inductance, then there's obviously something non-repeatable in the way you're winding them. If you get repeatable results that just don't match the formula you're using, try this:

```
/*
* solenoid - program to calculate the inductance of a solenoidal coil of wire
*
* based on the Technical Correspondance article
* "Accurate Single-Layer-Solenoid Inductance Calculations" by Hank Meyer,
* W6GGV, from QST magazine April 1992 (pp 76-77) plus corrections not yet
* published as of May.
*
* usage:
* with no arguments, prompts for number of turns, coil length,
* coil inner diameter ("mandrel diameter"), and wire size or gauge.
* Enter wire gauge as #16 (or =16) for 16 AWG; enter wire size in
* inches as a number, or mils by suffixing number with m.
* with 4 arguments: number of turns, coil length, ID, wire size
* all specified as above.
* with something other than 0 or 4 arguments, displays a terse usage
* message.
*
* This program written by John Woods, jfw@funhouse.com, 19 May 1992.
* All Rights Reversed (K).
*
* Requires strtol() and strtod() which are common pre-ANSI library
* extensions, as well as being official ANSI functions. This isn't
* necessarily the best code in the world, but it works.
*/

3254. how do you make the 10MBit microwave link from the 2MBit link?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-27 00:00:00 UTC
From: mlyon@walrus.mvhs.edu
Message-ID: <3v7874$a4d@news.arc.nasa.gov>
Source record: 111663

I have the 1991 ARRL handbook and i was interested in making this 2Mbit link. i have heard that this can be made into a 10MBit link somehow.I would like to know how it is done. Also if anyone has made this and interfaced it with ethernet i would like to hear some of the problems you encountered while building this and interfacing it to ethernet.

Thank You,
Mike Lyon

While you're all feverishly looking up sources, does anyone know
a formula for air-cored toroids? I wish to make a high power coil
for feeding an end-fed dipole and wire is cheap and toroids aren't.
Thanks in advance.
Murray Kelly. vk4aok.

I've built a microcontroller (8031) keyer from an 73 article. The
firmware was available from a BBS. I downloaded it and found that the
schematic did not match what the firmware was expecting. I also
found multiple bugs in the code.

I modified the schematic and modified the code to remove the bugs and
add features that I wanted (firmware messages, straight key mode,
more speeds, long space mode, MS message mode.....).

If the code was not available I could never find the bugs (the
bugs were hard to find, IE it "seems to work"), or add other
functions. I seriously doubt that anybody had built it from
scratch without consulting the author or the 73 magazine editors.

John,
This has been hashed over YEARS ago, read the archives.
The author chooses NOT to give away his work, I respect that.
On the other hand, I "do" Motorola micros, so I could write the
code in a day or so. Curtis doesn't give away it's silicon design.

I have mixed feelings about this sort of practice. On the one hand,
the firmware is the heart of this project, and the author has a
right to profit from its development via selling programmed chips.
On the other hand, QST is an educational service and its articles should
reflect that by fully disclosing how projects work, which in today's
microcoded world means including source to any programmed bits.

Ideally, I'd always want sources available for any microprocessor
controlled project. In reality, however, I'd rather know about these
products than not know, so publishing the articles is still of value.
I do think, however, in a case like the present one that the article
really should have been labeled a product review rather than a construction
project.

Yes, it bothers me. But what realy gets to me is that I looked at the design/features and at several points said to myself "that is so stupid, why didn't they do...." (for example the difference in price between the various serial EEROMs is now so low, why didn't they go for a larger EEROM, or at least have the option of using different sizes?). Now, anyone who want to do a better CMOS Keyer 3 has to start from square one, grumble.

In essance the QST write-up is just a multi-page ad. for a new hardware product (ie: the pre-programmed chip). Now, I don't mind multi-page, highly favorable reviews of products. I don't mind when Icom, or Kenwood, etc., buy multi-page ads.. I can live with firms that write articals about their new kits, but also provide enough info. that you could build the radio, etc., without puchasing anything from the kit firm. What does annoy me is these sorts of multi-page "editorial" ads for a product that force to buy from the author of the artical if you want to do anything useful.

How about QST (and the other magazines) bring in a policy along the lines of "If a component in a project is only available from ONE source, then the author of the artical can NOT have a financial interest in the component source". This way there is no threat of there being a percieved conflict of interest.

I am pleased to announce a new product offered by Positive Time Systems
called the RCS-I. This is a radio controller that connects to any VHF/UHF
transceiver and can issue x-10 commands. The unit also has an alarm
input, a listen feature, a short voicmail box, and responds to all
commands in a pleasant female voice. The system IDs with your recorded
voice and call sign.

This description doesn't do the product justice, so
please check out the new homepage at :

http://www.halcyon.com/pos.time.sys/top

or send email for more information.

Thank You,

Marshall Craw <mcraw@halcyon.com>

I don't know enough of the technical reasons as to why old tubes fail, but can say from experience that at least 70% of the glass tubes I saved failed within moments of using them. On the other hand, I have several metal tubes, some from WWII period that still work fine, even after similar length storage times.

It seems that the higher power rating of transmitting tubes, and the higher heater rating of receiving tubes is directly proportional to their shelf life. As virtually no tube rated for HV was useable and a few of the medium voltage tubes worked and most of the low voltage tubes were fine. The really really old gandy dancers seemed to all be OK, or at least the ones that I still had old Hallicrafters equipment to test them in.

Source record: 111667

My experience with 811A's is this:

Many of the 'Penta' brand tubes are pretty unreliable. I have had best success with the 811A premium tubes from RF Parts in San Marcos (SanDiego) they are fully tested, including RF testing if you want, and they have types fully inspected for use in horizontal mounting configurations.

I have a vested interest in this, as an amateur dealer I sell a lot of linears using 811A's (Ameritron and Vectronics). For some time I had lots of problems with the Chinese tubes, until I got onto the RF Parts ones.

They also offer a Russian version of the tube at a higher price. I haven't tried this yet. But I think next time I order tubes I will get a set and see if they are any better.

FYI, their details are: RF Parts, San Marcos CA, ph (619)774-0700, orders on 1-800-737-2787, FAX (619)744-1943 Chinese 811A's $38.90/matched pair, $58.35/matched triplets or $77.80/matched quad.

Actually Jim,
You'll find better regulation with PNP paralleled with
the 3 pin regulator. The be drop makes the regulation poor in the
conventional 3055 circuits. Better still, a power FET driven by a
723.

Source record: 111670

True, the circuit you mention with the paralleled PNP gives better regulation.
There's a benefit you didn't mention -- using a TO-3 PNP pass transistor, the
case of the transistor is at ground potential and doesn't require insulating
from the heatsink.

The rig I described it incredibly simple and easy to put together from
junk or from Radio Shack parts (same thing, IMHO). Regulation is adequate
for most simple ham radio/experimemter projects. As soon as I start finding power FETs in
the dumpster, I'll improve my "cheap and easy" power supply.

Dave;
I for one would be interested in you references. I would also be interested in the feasability of Homebrewing VHF amps. I realize that the voltages are very high and although I have been messing around with building I have yet to work with such voltages.
I would appreciate it if someone could give me the general idea of the scope of such a project. Are components readily available? How do I avoid blowing up EXPENSIVE power tubes?
You know little details like that!

Look at the newsgroups header. *One* of the groups to which this
message was crossposted is a uk.* group, but there's also a de
group, a fido group, an alt group, and two of the rec.radio worldwide
groups. I thought only Americans were supposed to be monolingual.

Gary

3279. M/C mic & headset

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-29 00:00:00 UTC
From: rogersmith@iquest.net
Message-ID: <DCI1ID.E7M@iquest.net>
Source record: 111588

I'm looking for ideas on how to construct an in-the-helmet mic/earphone setup for my fullface motorcycle helmet. I have a Alinco DJ-180 H.T. and have tried using Alinco's VOX lapel/earplug unit without success. Even on PTT the mic was too sensitive and the earpiece was too "squeeky", so all either side could hear was distortion.

Any suggestions would be appreciated ! ..... Roger N9PMC

As far as I know, all of those numbers are current and any Motorola distributor should be able to supply you with the quantity you want.

You may have to wait a bit, as there is an industry shortage of Power MOSFET silicon, but get your order in. Better yet, call Motorola marketing in Phx. The switchboard number is (602) 244-6900, ask for Power Marketing, and see if they can't check their distributors for the parts you want.

For what its worth I sucessfully built the 4cx1000a 2m pa from the arrl handbook.The use of grounded screen is a very good idea,not only from the view point of stability but also a good base is hard to find or very expensive.You can probably find one with a damaged screen bypass cap and fabricate your own base.I think it will be very tricky to get a bandspread(term???) of 160-6m.There was a design in the arrl handbook for a 4cx1000 on 6m I seem to remember that the output coils inductance was varied by compression and expansion.I think its a very good idea and saves on a high voltage variable cap.The nice thing about the 4cx1000 is the low drive requirements.I can get well over 1.8kw with 25 watts of drive into a dummy load of course on 2m.I dread to think what gain you could achive on 6m.This gain makes for low tolerance of feedback paths so careful construction is necessary. If it were me I would use the 4cx1000a on 6m and get a big triode for the hf amp.

Well Qst is much more than a magizine. It is the publication of the
national ARRL organization. The magizine is the journal which comes with
membership. As such it should have different/higher standards than other
for profit publications. As a mater of fact I can't just not publish the
maggizine. And the fact of the mater is that in these types of
situatations I would more than likely get the pre-programed part if I was
to build the article. However as any future repair is out of the question
as the part will not be available in the future I wouldn't consider
building this project. There are enough things to buy that you can't
obtain ther repair parts that I'm not about to knowingly build any more.

Again thats all well and good but it shouldn't be in the journal of the
of the national association. Be great in 73 but the purpose of QST is not
to promote one individuals profits. It is much like the articles that
have been in some of the hobby magizines that show a part as box and when
you get the project they have sanded the designator off the chip. This
would have never been accepted in QST.

> Kenwood or Icom.
I have never seen any article in QST posing as a construction project written by ICOM or Kenwood or even Heath in thier day. Product reviews yes. Product reviews written by the company posing as a construction article , no. If you have any examplles please referance them. I have a pretty good source of QSTs.

And it was in this case an individual. A large company would have been just as bad.

I mean QST wouldn't even publish articles using a PCB unless you made the artwork available. At least that was my understanding. If it wasn't policy it has been custom for many years. You might have to send to the ARRL for it but the artwork was available.

I guess my point is is this a product or a construction article? In my own mind I can't accept it being both and believe the differance is key. If its a product then let you obtain it from the manfacture and then write of your experances. If its a construction article then let you build ,expand, modify or whatever and let the author write it up.

It does "sort of" bug me! I agree that no one should be able to take
the firmware code and sell a bunch of programmed MPUs BUT in the usual
spirit of amateur radio, I think that making the code available for
"personal use" is appropriate. Another responder suggested that the
article be labelled as a product review rather than a construction
article - also a reasonable suggestion, since without the code,
the project is useless.

Many other magazines has articles on MPU-based projects and make the
code availle via BBSs, etc, and I bet that the authors still sell
a lot of pre-programmed units. My vote goes for making the code
available for "personal" (not commercial) use or else don't give
the article the honour of being a "do-it-yourself" piece.

The dipper will work as a simple receiver. If you had some noise (AM)
in a transmitter somewhere, you could listen to it to find out where
it was coming from. You'd probably set the meter adjust knob to
minimun in order to use it that way. Checking the various stages by
pulling the tubes out one by one. You remember what a tube is, don't
you? 8-)

You can check crystals for activity with a dipper. You can prune an
antenna to get it close to resonance with the help of a dipper. You
can check to see if an RF choke is doing what it should do at the
frequency that you're going to use it at. A buddy of mine used his
dipper to check the resonance of a big washtub once. It worked like a
big cavity resonator.

Jim

If memory serves, the 4264 has the same pinout as the older 4164. The 4264
does have some internal differences, but the basics are the same for simple
read and write cycles.

I think that I have some of those around somewhere too.....Jay

3294. re: Why variable BFO?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-31 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <1a6_9508061528@mba.mba.org>
Source record: 111474

ian.mitchell@research.utas.edu.au (Ian Mitchell) is wondering
why the low cost shortwave receivers have tuneable BFO's while
the more expensive ones have a LSB/USB switch.

I would think cost has a lot to do with it. If you assume that
the switch selected BFO's are crystal controlled, then the cost
of the crystals is not warranted for inexpensive sets. IN the
early days, I'm sure all BFO's were tuneable, and then only later
did crystal control arrive. Thinking about it now, crystal controlled
BFO's probably didn't show up in amateur receivers till receivers
intended for SSB hit the market, and they were of course the
expensive receivers. The low end receivers have basically stayed
the same.

One reason for going to crystal control of a BFO was the ease of
switching between the two sidebands. When the receivers started
getting sharp filters intended for SSB, you wanted the BFO right on
the slope to take advantage of the sharpness of the filter. If
the BFO's had stayed tuneable, you'd always have to keep fiddling
a bit each time you changed sidebands, to get that exact spot.

And yes, your thought about the selectivity of the receiver probably
does play a part. The cheaper receivers would tend to have filters
with not so sharp curves, and there is not the need to get the BFO
right at a certain point.

When you start using a receiver with the relatively wide bandwidth
intended for AM broadcast, you you could put the BFO right in the
middle of the passband and you wouldn't even have single signal
selectivity. It would be like a direct conversion receiver in that
you'd get the audio image, but with better dynamic range due to
there being selectivity, albeit wide, between the antenna and the
product detector. A tuneable BFO in this case would have the effect
of a fine tuning control, just as tuning the "BFO" in a direct
conversion receiver tunes it across the band.

I have thought of the possibility of building a "hybrid" receiver,
where the first mixer would be fed with a synthesizer with something
like 5KHz steps (it's easier to build a quiet synthesizer as the
tuning steps get bigger), then put it through an FM-type crystal
filter at 10.7MHz, and either put a direct conversion receiver
after that or a second mixer with a 5KHz tuning range to take it
down to lower frequency final IF where there is a narrow filter
and product detector. It would be a way of getting a relatively
simple general coverage receiver, but with the advantages of
synthesizer tuning.

I remember seeing one receiver in QST from about 1958 or so (the year before I was born, so I read it a number of years later) which was a single conversion six meter receiver. It used in the IF a then relatively new item, a manufactured crystal filter in the HF range, and having something like a 4KHz bandwidth. It used a crystal controlled BFO, which makes sense since it's easier keeping a crystal on frequency than an LC-tuned oscillator. But the BFO was right in the middle of the IF. The idea being that the filter was wide enough for things like CW and even SSB that you could tune the receiver until you got the right beat note and everything would be fine.

I hope that helps, and I'm glad you found the 10.245MHz crystals. I'm not sure how the Australian dollar converts to Canadian these days, but the price you mention sounds not too expensive, which is the right price.

3297. Current balun

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-31 00:00:00 UTC
From: mkelly@brisbane.DIALix.oz.au
Message-ID: <3vg7dpmgl1@brisbane.DIALix.oz.au>
Source record: 111603

I have read about current baluns made from a length of coax fitted
with many small toroids as a *balun* and have wondered why, if they
are so effective, somebody doesn;'t make a cable with the ferrite
built right in to the outer jacket.

A small amount of ferrite powder (available) of high Q would stop
flow of RF currents in a mis-match situation right from the start.

The effectiveness of toroids is proportional to the radius / against
the diam of the conductor. ie the closer the better. Hard to get closer
than the outside shield. Then you could summarise the total effect
as being like a great long stack of toroids between the benerator
and the load. (sorry about the typing!!)

In this situation a little hi Q would go a long way. To suppress
RF that is. Putting the ferrite right on the outer shield would stop
skin currents dead. The Coax would work as theory predicts, and
radiation reduced considerably. (?)

Does anyone know of such a product? I know that ferrite powder
is cheap and can't figure why, with all the interest in
current baluns, it isn't available. We all know we rarely have
a perfect match generator/load and any help would be appreciated!

Esecially with the neighbours I have.

Thoughts please?

Garry> the national ARRL organization. The magizine is the journal
Garry> which comes with membership. As such it should have
Garry> different/higher standards than other for profit
Garry> publications.

I've read magazines that do have different or higher standards. They
don't accept free evaluation hardware, they don't accept advertising,
and they struggle, but I have little doubt of their integrity. While
I approve of the ARRL and enjoy QST immensely, I am less sure of their
freedom from bias. Bias is not a great evil, IMO, but it is something
I always want to know about.

Garry> As a mater of fact I can't just not publish the maggizine. And
Garry> the fact of the mater is that in these types of situatations I

Garry> things to buy that you can't obtain ther repair parts that I'm
Garry> not about to knowingly build any more.

I'd say the decision to build the project or not is always up to you.
I'm fairly frustrated that the code isn't available, myself, but I
consider that to be the producer's prerogative, and I don't grudge him
that. And I'm glad that QST chose to publish it, because it gave me
some ideas.

Bob> [...] magazine for that matter. Not liking the article, or the
Bob> fact that they don't want you rolling your own, is one thing, but
Bob> this is the way software/hardware makers make a living, just like
Bob> you or I.

Garry> Again thats all well and good but it shouldn't be in the
Garry> journal of the of the national association. Be great in 73 but
Garry> the purpose of QST is not to promote one individuals
Garry> profits.

Is this as opposed to the profits of a corporation? I notice that there are an awful lot of articles that show the technical details of commercial equipment for which there is one ultimate source, namely Kenwood or Icom.

It is much like the articles that have been in some of
Garry> the hobby magizines that show a part as box and when you get
Garry> the project they have sanded the designator off the chip. This
Garry> would have never been accepted in QST.

I posted on this thing before, but I want to state that my feelings are
about the same as Gerry's. I also feel strongly that an author has
the right and privilege to prevent copying his product, but this was
NOT a construction article. Even the cover of the magazine had a
misleading statement - "three simple projects to build this weekend"
Well, by the time I order this semi-kit, the weekend would be over
and gone! If this continues, I may have to re-think my membership
in ARRL. Anyone know how to retract my life membership?

3301. Re: Winding coils

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-31 00:00:00 UTC
From: acatalan@nyc.pipeline.com
Message-ID: <3vhpkl$f27@pipe2.nyc.pipeline.com>
Source record: 111607

About coils in general... I have built a few dipoles involving coils.
When they are placed at a hight current/low-voltage point they can become lossy/lousy. [near the center of a dipole/ at the base of a mobile whip(common)]
When they are placed at a low current/high voltage point (at the end of a dipole/at the tip of a whip) they tend to act more like a capacitance. Also in this case you will find that mathematically the amount of inductance needed may approach a very large number.
I like to place my dipole shortening coils right at the middle of each of the dipole legs as a very "happy" compromise between these extremes.

3303. Why variable BFO?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-31 00:00:00 UTC
From: ian.mitchell@research.utas.edu.au
Message-ID: <3vhlvb$7u0@franklin.cc.utas.edu.au>
Source record: 111609

Has anyone noticed that the low cost SW receivers use a variable
BFO for SSB reception, whilst the more expensive ones have a USB
LSB switch?

Is this because of the bigger frequency tuning steps in the lower
cost receivers? Or does it have something to do with the bandwidth
of the IF filter for SSB?

Also, I would like to thank all those who have responded to my
questions so far, thank you! BTW, I have found a good source of
10.245MHz crystals in Australia. You can get them from Hy-Q International
Australia Ph (03) 9562 8222 for $1.80 each + tax.

I am on amajor crusade to eliminate rfi coming from my computers that is getting into the HF rigs. I am looking for a good source of toroid beads, snap on chokes, and ferrite cores for fighting this stuff.

I have some information on Palomar Engineering, and Radio Shack, but there products seem to be over priced (I think).

Does anyone out there know of any good sources for these types of products with really good pricing?

Any help would be appreaciated.

Thanks.

Well in a nutshell because the bfo is much cheaper to produce.\,
therefore its used on the lower cost rtecievers.

Actually I should say tunable bfo. Most of the lsb/usb switches are just
selecting two bfo frequencys. However to be switch selected they must be
quite stable and match the if. Also as you suggust with wider tunning
steps a variable bfo can fill in the steps to give the effect
of continous tunning for sideband.

Okay, bad example (;->=). Oops...

Garry> Product reviews yes. Product reviews written by the company
Garry> posing as a construction article , no. If you have any
Garry> examplles please referance them. I have a pretty good source of
Garry> QSTs.

Me, too. The library my office is in has about the last million
years' worth of QSTs on the shelves (I'm exaggerating, natch!).

Garry> And it was in this case an individual. A large company would
Garry> have been just as bad.

If it's bad, I agree. I think the same standards _ought_ to be
applied to everyone. I don't think it necessarily is, however. Just
my opinion, of course; your mileage may vary.

Garry> I mean QST wouldn't even publish articles using a PCB unless
Garry> you made the artwork available. At least that was my
Garry> understanding. If it wasn't policy it has been custom for many
Garry> years. You might have to send to the ARRL for it but the
Garry> artwork was available.

Working from memory I may be mistaken, but a couple of months ago I
did some extensive reading of back issues of QST looking for
construction projects (I started with the then most current issue and
worked backward about thirty years), and I seem to remember several
articles which had pre-programmed EPROMs that were only available from
one source. While I don't recall if any (or all) were written by the
programmer, I distinctly remember thinking on at least a couple of
occasions "Well, it's been x years, and I'll bet the address isn't
even any good any more, and I doubt seriously if the author still has
EPROM code...or EPROMs, for that matter."

I'm not trying to get into a contest with you; but I have a different opinion on this issue. To me the project is a construction project, though it would take a braver soul than me to try to duplicate it completely, since I'm a pretty awful programmer. OTOH, I might attempt it just for the challenge of it, since the author gives a pretty complete description of the functions implemented.

I'm in the same boat with another project that I'm much more committed to. I want to build an OptoSCC card for packet under Linux, and I have the schematics and text articles, and even parts-placement diagrams. What I _don't_ have is artwork, or a source for the programmable logic array it uses, or the programming information for the PLA. I spent a lot of time and effort trying to get the designer's e-mail address, and finally succeeded, but haven't received a response from him on my request for information/help.

In this case I'd consider buying the board and PLA from the guy (I think the board is two-sided), but I can't get a response back.

On a side note, I wonder how the author of the software for the keyer would be respond to the proposal to release code for a simpler-minded version of the keyer for free, so that people could get a functional keyer without buying from him, and if they liked it they could buy an upgrade. That might tempt me both to build it, to tinker it (if such were my inclination), to replace the EPROM with his if I liked it and wanted more functionality, etc.

Garry> I guess my point is is this a product or a construction
Garry> article? In my own mind I can't accept it being both and
Garry> believe the differance is key. If its a product then let you
Garry> obtain it from the manfacture and then write of your
Garry> experances. If its a construction article then let you build

With the dipper power off, they can often be used as a wavemeter. The audio
out might be from an RF detector, so you can hear the modulation when using
it as a wavemeter.

: >
: What bothers me is not the fact that THIS keyer has propriotary
: microcode, but that QST presented a "Construction" article that
: the builder has no choice but to order the part(s) from a single
: source.

I can tolerate the single source bit, but not where the author of the
item has a financial interest in the source. For example I could live
with an item by an Intel engineer about a weird but very usefull chip
only available from Motorola. What I cann't stand is a person who whites
an item about a chip that you can only get from the author.

: I would like to see a functional equivalent keyer published that
: provided similar functions and made the source code as well as the
: compiled version available so we hardware (and firmware) hacks
: would have a guide to start with when we don't have the time or ambition
: to do the whole thing from scratch.

Agreed.

: In the spirit of ham radio, lots of us have shared our code with
: others - remember freeware. I think we would further the state of
: the art with ham radio a lot more by encouraging experimentation
: like playing with the code for a keyer than the published alternative
: of just buying the thing and soldering the parts and creating a box
: to put it in.

Putting stuff out under a copyleft (ie: the Free Software Foundation's
copywright) would be good.

Saturday, at a local Hamfest/fleamarket I purchased a dipper. This thing is old, the markings on the box mention a frequency range of 400 Kcps to 280Mcps. It appears to have had a number of owners, one in Beaumont, TX and a another with a VK call that are obvious. It still works tho, and still has all of its coils. I have a couple of questions about its use. I know about the use of a dipper to check the resonant frequency of L-C circuits. I also know about using one as frequency source. What other neat uses of a dipmeter are there? Also, this unit has a place for audio out. It came with an earplug, It may be dead, but the jack is still live. What is the audio out for?

If it's something you drew yourself, rather than scanned, why not post
in HPGL. Most drawing programs have HPGL output, and it's all ascii, so
no need to encode.

It certainly bothers me. I think of QST in somewhat the same light that
I would look at the IEEE proceedings; as a publication to share and
distribute state of the art information to the benefit of all. As such,
if QST publishes a construction article, then all of the pertinent inform-
ation needs to be included. If it is simply a review article of something
that can be purchased, then publish it as such, and let the construction
details be included with the purchased materials.

A similar situation occurred a few months ago when QST published a microwave
receiver article that included everything but the PCB pattern. The only way
to build the rcvr was to buy the board, because it included several microstrip
components that were not shown on the schematic.

I hope that this trend does not get any worse.....73 de KI7RH

Yes ... and no. Most 'high end' transceivers now include a variable CW offset feature -- implemented in a complicated way to give the effect of a very simple feature -- variable BFO frequency.

Fixed frequency BFO's are not always the best answer, nor do they necessarily reflect "higher cost" as far as the receiver is concerned.

Another good place where they can be used to advantage is in tailoring the audio passband response in a filter-type SSB generator. Placement of the BFO frequency relative to the filter passband gives more or less highs/lows in the transmitted signal

A good, stable, variable BFO could easily be more expensive to produce than a plain-jane oscillator with a couple of switchable crystals for sideband selection. And is much more versatile.

>Any suggestions would be appreciated ! ..... Roger N9PMC

I used a Honda CB-400 Hawk for commuting for a year back around 1981.
The radio was a Midland 13-509 crystal-controlled 220mhz unit (packaged
like a 12-channel CB radio), and I used a slide mount on the handlebars.
I ran mobile only for about 6 weeks before I had a accident, and I
figured safe commuting and life & limb preservation was more important
than ham radio. Also my car was going back together rather well, and
I could see getting back on four wheels rather quickly.

Anyway, I used a spare mic element embedded into the pad of the chin
guard, and a contact speaker attached to the helment with hot-melt glue.
I specifically hunted up a duplicate cartrigde and duplicated the mic
wiring so that electrically itlooked identically like a hand mic.
The contact spealker takes a bit of explanation: there are speaker
drivers without cones that are designed to bolt to walls and turn
the walls into speakers. I used one of those on teh helmet itself.

I cut the wires to the starter button, and spliced in a dpdt toggle
switch, with the wipres going to the switch and the contacts of one side
going to the original starter wiring, and the contacts of the other side
going to the PTT leads. This gave me a easy to reach PTT.

Make sure that you use a pull-apart connector on the helmet headset -
the last thing you need if you have to abandon bike is to be tied to it
by your helmet. A molex like what is used for the power connector on a
3.5" floppy is just right. The ones like are on a 5.25" floppy are a
little too tight fitting for me.

Make sure you waterproof all teh equipment and wiring - even if you are
in a dry area. My rule of thumb is that if it is waterproof, then it's
probably dustproof.

I'd be interested in how things work out.

;>
;> Grant/NQ5T
This may all be true Grant but the question waas why do cheap recievers
have BFO and good recievers have selectable sidebands.
TYhe answer is that cheap recievers have cheap bfo because they are
cheaper and work better with limited recievers. They certianly don't have
bfo's because they are more complex and cost more.

And switchable frequency beat oscilators don't work at all unless you
have very fine tunning steps 100 Hz min and 10 Hz preferable

The best selectable sidebands change the filters not the beat frequency.

Garry
WB0NNO
Actually anymore gome of the real expensive recievers change the software
to select the sidebands with a DSP unit running at the last IF.

For using it as a passive wave meter. Use it with power off to check for the pressance of RF.

Garry

Don Josnsons book "40 + years of HF Mobleing" has a reprint of one of the clasic Grid Dippers operatung manual. Probablly worth the price of the book which is about 15.00 from world radio. I've only glanced at that section but it looks like it really gets into the use of a grid dipper.

3324. CMOS Superkeyer 3

While you guys argue the merits of the whole thing being in QST in something other than a product review (I'm not sure how I find out about it if it's not in there), several folks have ordered and constructed the project. Our club used the orginal SK2 as a club project and had barrels of fun making it. Out of about 30 I know were constructed, no one ever brought up that they felt slighted because they didn't have the code. The orginal was in 1990 ? QST and it is absolutely the best keyer I have ever found. Of course, I made many constructional variations in the packaging - 1 1/2 x 2 x 2 1/2 inch bud case polished off on a buffing wheel to shine line a mirror. A set of 3 AAA batteries last about a year in regular operating. We had about 30 variations on the packaging and everyone enjoyed showing them off at the club. BTW I plan to order the SK3 and install it in one of my QRP rigs. I suspect that the proceeds from the SK2 of which I think about 5000 were sold, probably had something to do with their producing the SK3. An occasional proprietary code project as good as this one certainly seems fine to me.

>of the IF filter for SSB?

While the coarse tuning steps of some of the cheap synthesized radios make a tunable BFO convienent, that doesn't apply to those using analog tuning (and RIT could be added as easily instead). The real reason they use a BFO is that it is a *cheap* way to convert an AM only radio to quasi-SSB reception. Since most cheap SW receivers are primarily intended for SW broadcast reception, which is AM, tacking a BFO in there adds a "feature" without costing the manufacturer much. (Of course with the broad filters used in an AM rig, you really don't get *single* sideband reception. The image frequency is still in the passband of the IF filter.)

A quality SSB receiver will have a narrow IF filter with a good shape factor so that only one sideband will be received at a time. Since the filter is matched to the signal, there is only one frequency on which the carrier re-injection oscillator can work for USB, and one other frequency for LSB, so switched crystal oscillators are generally used instead of a tunable BFO. The IF filter is generally the single most expensive component in a quality receiver, a couple of crystals are cheap by comparison, and their stability means you'll always be on the proper slope of the IF filter for the mode selected.

Speaking of keyers, has anyone built the keyer on the cover of the June issue of 73? It's a alarm clock, keyer, and code reader all in one, and it's also based on a preprogrammed microcontroller you have to buy from the author.

A dipper can also be used as a wavemeter to measure the frequency of
an operating source if the oscillator is stopped and the coupled RF
is rectified and fed to the meter instead. That's what the diode
position does. When used this way, you tune for a peak on the
meter instead of a dip.

You can also use your dipper as a crude frequency meter with the oscillator
running, if it has a headphone output. Just tune it near an operating signal
source while listening for a "beat" note on the headphone. Zero beat, and read
the frequency off the scale.

In either wavemeter or frequency meter mode, the dipper will act as a
crude receiver for AM modulation, so you can use it as a modulation
monitor too.

Source record: 111487

I have tested 450TL's built before WWII, and they are perfect. Also,
other glass xmitting tubes, such as 100TH/TL, 813, etc, which have been
lying around for decades and still unused. They were all perfect, and the
transconductance and characteristic curves were within specs. I have
also found new, unused (in original boxes) receiving tubes, such as as the
30, 41, etc. They likewise tested like new. I have
concluded that the shelf life of these kinds of tubes is INDEFINITE. Tubesdo
not normally become "gassy" except through the outgassing of the internal parts
due to elevated temperature. That is why xmitting tubes are pumped down while
their elements are red-hot (by passing large currents thru them). It is
fun to test these tubes, and plot their characteristics. I have contemplated
making my own tube out of parts from broken ones, and pumping it down
and resealing the glass envelope. "Final here uses a W6JL-1 triode, OM"....

Certainly, as I am fond of pointing out, you don't have to know
what is inside a black box to use it effectively. However, the
Super Keyer II and III both frustrated me in that the internals
are completely obscured. Most black boxes I use have data which,
at the minimum, describes the internal architecture. I generally
look at QST construction articles as a way to learn; I can learn
much without building something by looking at the diagrams and
reading the text. I learned nothing about building a CPU based
keyer from reading how to use the SKII/III.

I personally think one of the areas that amateurs are falling
behind the most is in embedded system design and development.
This is probably why the omission of any design notes at all
for the SKII/III irritates me the most; here's a project that
could spark interest and learning in many amateurs about a
very important technology, but it won't spark any learning
to speak of.

If I had more time, I'd love to develop some ham widget and
article for QST, which exposes how embedded processors are
used, and how a design can be implemented partly in hardware
and partly in software. I'd also love to see QST increase
the standards for construction articles to always require
a description of the internal operation of any "black box".

3331. Super CMOS III keyer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-01 00:00:00 UTC
From: adams@chuck.dallas.sgi.com
Message-ID: <3vm4md$lo4@murrow.corp.sgi.com>
Source record: 111490

Gang,

I bought the above, received it in short order, assembled
it in about an hour, and have it on the air. A fan of
the CMOS II and now the CMOS III.

I don't remember seeing too many people complain about
the Curtis 8044ABM chip being from a single source with
no internals given out, yet it's used in a lot of rigs.
Also used in keyer kits and used in other projects at
around $17-$19 US per chip.

I've seen the arguments on both sides about the article in QST,
but let's look at the big picture. If you had spent several
hundreds of hours refining the program and debugging and
getting opinions of others on timings, message storing,
board layout, and paying Motorola the big bucks to get
the chips made up, wouldn't you do the same thing? It
may look like a weekend project but it's not. Just look
at the documentation, it's pretty good. No assembly
instructions, but hey, we're radio amateurs here.

I'll pay you a $58 for the same thing with the source
code. Would you sell? You'll be out more than that
for the development, time, and parts.

I'll tell you what, the circuits already there, let's
have a race to see who can reproduce the code. Any
takers? BTW I'm not in the race, I'll stand back and
watch. Unless someone has a lot of time on their hands
I don't think this project will get done. Just let the
rest of know when you start and when you finish.

Going back to the ARRL and QST. Just how much of the
magazine is advertising? A lot and it will have to
remain that way for them to keep printing it monthly.
The race between ARRL, 73, CQ, and the others is for
advertising dollars. There is no getting around it.
Besides, where else are you going to find out what's
new and the prices (except for the "CALL for QUOTE"). :-)

I've done a keyer using the 8051/8031 series but I
went with EPROM and RAM, thus more board space and
more power consumed. I learned from the project and
I will let it go later and will post it on the qrp-l group.
This means schematics, PC board, and code listing. Such

a project will take up too much room to publish. Oh you say, just put the code at an ftp site, but what about the guys/gals not on the "superhighway"? It's just too much trouble for most authors and there are always those readers and subscribers that say they can do it better, faster, and cheaper. Fine. Just do it. (I think that's Nike's slogan).

The point: I see a lot of "consumers", but few will become "producers" and fewer will give it away.

Wayne Burdick, N6KR, designer of the NorCal 40a and the NorCal Sierra has a PIC based keyer due out in October that also serves as a freq counter to output via audio the last three digits of the frequency (thus another reason to learn the code). It is a commercial venture and a neat idea. Few will know about it and fewer will wind up with it as it doesn't "plug and play" in the Yaesu's, Kenwood's, etc. I'm sure you won't see the source code anywhere either. We know what happens to source code.

Another note: on parts and availability thereof. I see an ever dwindling supply of parts except from Mouser, DigiKey, and a few others. If you go back even 10 years in QST, 73, and others you'll have difficulty in finding some of the parts. Look for a cheap source of the larger electrolytics at high voltages! It's part of life in the technology driven era of mankind. We also keep losing yearly the small businesses that are operated on small margins from the garages of America and other countries. The "big" industries are just making it too cheap to be a consumer and as a result generate more and more so called "appliance operators", individuals who operate the equipment but only know a small part of how the system works. Not a complaint on my part, just an observation. Mail order is expensive anyway - just look at the cost of just a first class stamp now in the US. UPS and Fed-X aren't cheap either. Add in phone expenses, ... You get the point.

They can take the soldering iron from my cold dead hand. Build 'til you die and homebrewing is still alive and well. Same for kit building as long as they make 'em. I still have a Heathkit SB-104A in the box. It'll be the last one.

dit dit (soap box off - flame suit on)

IG>If it's something you drew yourself, rather than scanned, why not post
>in HPGL. Most drawing programs have HPGL output, and it's all ascii, so
>no need to encode.

This is something I've wondered myself. If we do some homebrew project,
can we share it with others in this newsgroup? So far I've only seen
people talk about homebrew, but never share any plans.

I've just designed and built a voice keyer for my shack using a digital
voice module available at Radio Shack for $19. With the addition of a
few additional parts you have a complete voice keyer that will key the
rig by itself, uses your station's mic for input, and records/plays up
to 10 seconds of clean audio. The project is similar to the April '95
QST article to build a "$15" voice keyer, but I think my design is a
bit nicer :)

I'd be happy to post the schematic here or to anyone that wants it, if
there is interest. I can make HPGL or Laserjet output files. I don't
think I can create a .PCX file though.

I am looking for the address and fax number of QEX magazine so I can subscribe. I am particularly interested in an article published in the June 1993 edition on measuring SINAD with DSP.

Any help would be appreciated.

Cheers Jonathan

Well I hope you feel that way when itr fais and he got tired of fooling with it. Besides the profits of the 5000 you refer too was made with the code bring available.

Ramsy(Ramsey) has made 1000 of kits but I sure hope they don't become QST's idea of a construction article.

I'm working on a microwave camera using mechanical scanning and an old cop-radar detector. This is strictly at the hobbyist level. I hope to be able to record slowscan stills of conductive objects scattered about in a transparant insulating environment. Should be interesting. Anyone here ever heard of such a thing? Microwave mavens have any advice? I'd like to eventually try something better than 10GHZ, if I can find a source for emitter and detector devices.

I'm designing an off-line convertor to provide plate potential for several other devices and I need a source for gate turn-off SCRs. These need to be able to switch about 10 A avg and be able to tolerate at 750 V peak-reverse.

If you know of a dealer or distributor which can sell these in small quantities, please reply by your choice of means.

thank you for your attention.

>bfo's because they are more complex and cost more.

I don't understand. You don't need fixed frequency BFO's to have selectible sidebands. Many radios use one BFO and have TWO filters, one for LSB, one for USB. You kind of missed the point. At 455KHz (typical IF frequency) fixed frequency BFOs are more stable, but that doesn't mean there is something inherently more costly or "better"in a fixed frequency scheme. At lower IF frequencies (50,60 KHz) crystal controlled BFOs are not all that practical anyway -- and the BETTER gear that used these frequencies provided control over the BFO frequency.

>
>And switchable frequency beat oscilators don't work at all unless you
>have very fine tunning steps 100 Hz min and 10 Hz preferable
>
Patently untrue.

>The best selectable sidebands change the filters not the beat frequency.

Some receivers do this as I stated above. BUT, there is still good reason to have the BFO frequency variable under operator control for the reasons of audio response setting that I stated in my first reply.
>
> Garry
> WB0NNO
>Actually anymore gome of the real expensive recievers change the software

>

Interesting, isn't it. We're back to the PHASING method of sideband generation/detection again. Only difference between these "real expensive" units and the early sideband rigs of the 50's is a wee more sophistication in the application of Norgaards principles of the phasing method.

Grant

>of the IF filter for SSB?
The el-cheapo BFO is simply a carrier injected into the AM detector.
I did the equivilent with an AM only portable SONY simply by placing my
grid-dip
meter around 455khz nearby. Opposite sideband rejection was non-existent.
A true USB/LSB receiver implements a narroband filter where the incoming
455khz
signal is shifted a bit up or down acordingly by mixing one of two crystals
(usb/lsb)
to provide the needed selectivity to reject the opposite sideband.
This method of true ssb reception is much more expensive to manufacture
than the
simple BFO method that usually works ok untill a nearby or opposite
sideband signal
appears.

I've used one before. It was a 94GHz millimeter-wave imaging system. A little higher in frequency than you're doing, but the same idea. It also was a mechanical scanning design due to the single reciever design. At 10 GHz though, I don't think you'll see much. The 94 GHz system that I worked with used 94GHz frequency because of the fact that 94GHz happens to be a frequency that passes through normal atmospheric conditions with less attenuation than most other frequencies. Also the human body happens to emit in the 94GHz region as well. It is similiar to the 3-5 um and 8-12 um infrared-bands, but with far less resolution due to the lower frequency, but it can peneterate things that IR cannot, such as fog and even thin walls perhaps. The images that we got were very poor by todays CCD camera standards. You could make out forms such as people, cars, animals, and buildings but beyond that no further recognition was possible. So at 10 GHz I think your going to be very disappointed, but it does sound like a fun project and I wish you the best of luck.

E-mail me if you want to know any further details,

I'm interested in building a low power crystal controlled CW transmitter for
for the 2m, 220 MHz, or 70cm bands. (radio to operate on one freqency only...
the 220 band would be nice, but I'm interested in the others as well).

The application is a low speed data link involving microcontrollers and
PC's...I want to keep it as small, light, and inexpensive as possible.

I'd appreciate any leads on schematics, plans, kits, etc.

Thanks,
Eric.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.equipment

Ground score!
I found an antenna rotor, but have little not no info.

Does anyone have/use/know about the channel master crown. I got
it from someone who was reroofing --complete with tripod for the
roof, but I do not have the controler, and I do not even know the
voltage it needs (my guess is 12v). All I can see are the three
wires used to control it.

It is real old, but fits nicely into me new budget; it was free.

..any help or references appreciated.

Dan Drumm

All

I have aquired an old GE UHF HT. It doesnt have a model number
but it has the number 121A MP1 Series. It has 2 channels in the 450 Mhz
range. Can this be converted to Amateur use? Is it as simple as changing
crystals. How hard would it be to build a VFO to replace the crystal.

On this note, I remember seeing a page or two on the Baycomm Web
server discussing a modem that had been implemented with a
microcontroller and software...three chips total, I think. I couldn't
find it the last time I visited, but the idea intrigued me. If I only
knew a _little_ more than I do, I'd be interested in using this method
to implement the modems I'm hoping to need to go with the OptoSCC I'm
hoping to have. In fact, I'd be interested in doing this even without
knowing a little more: I can follow simple instructions...

Ditto. And if anyone has any references that might point the way for
a project like the one mentioned above (I'm especially interested in
PSK satellite modes, but would be intrigued by almost any
implementation), please let me know.

The question is...can you duplicate the microcontroller or get the
eprom image from their BBS? That's what steams me the most about the
QST article. Many can duplicate the QST keyer for much less than $55.00
but the author(s) and/or Idiom Press locked out that possibility. Having
the source code isn't necessary to duplicating the keyer and that
doesn't appear to be the prevailing issue of this thread.

John

I'm posting this for a friend with no net access, excuse me if i'm vague (his topic, not mine)

My friend is looking for the source code/file for a Philips FM 900 radio. He tells me to write that it's 8602 source code.

Ring any bells with anyone?

Please reply via email to st95169a@pilot.stu.cowan.edu.au

Thanks,

Gary.

Well Murray,
Do you expect the cable manufacturers to be :
Should they "know" what frequency your going to use their cable for?
Should they "know" what length to make your cable?
Should they "know" what power level your going to use?
Should they "know" what attenuation you consider adequate?

The torroid materials have a frequency range!
They have a finite power handling ability/volume!
They have finite attenuation characteristics.

Enough?

Tom

It was my understanding that some segment of the longwave band had been set aside for license-free experimentation, provided you stayed under a certain power level. In fact, I have vague memories of an article for such a transmitter in a back issue of Radio Electronics (or some similar magazine).

Does any one know the rules regarding longwave experimentation? Is there a web site for this sort of data? Please email any responses.

Source record: 111520

Yes, it is as easy as changing crystals.... but you will
have to align the transmitter and receiver RF &
oascillator/driver stages for best sensitivity and output.
If the original frequency is between 450 and 460 MHZ this
is likely all you'll have to do. If it is much above 460
MHZ you may well not be able to align it to specs without
modifying it by changing capacitance values in various
stages in which case you'll certainly want a repair manual
for it. Depending on what model GE it is, it may be one of
the series that employs a completely separate receiver and
transmitter, that might make it easily made into a low
power repeater.
VFO's of course are possible but very hard to keep stable
enough for satisfactory operation at these frequencies.
The necessary VFO output might be as low as 36 MHZ but
since it is multiplied in frequency by subsequent stages
whatever instability or error occurs is also multiplied by
a like amount.

You can build a single chip 2m Rx with the Philips TDA7000. It will be
out of spec. but I got one to receive 2m packet without any problems. They
are intended for VHF/FM broadcast reception.

>than the simple BFO method that usually works ok untill a nearby or opposite
>sideband signal appears.
>Anthony G. Catalano WW2W

Ok, does that mean in a low cost receiver with a not so narrow IF filter, a fixed frequency BFO (frequency set to middle of IF) could be used to resolve an SSB signal, regardless of which side band the signal is on, as long as there are no other nearby signals?

And presumably small tuning steps would be a necessity.

Thanks, Ian

3367. Re: August QST CMOS Keyer 3

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-02 00:00:00 UTC
From: dbeach@kean.ucs.mun.ca
Message-ID: <1995Aug2.110432.1@noah>
Source record: 111526

I realize that the 'CMOS Superkeyer III' exchange and QST bashing is almost reaching the flogging a dead horse stage so I think I will pursue a slightly different aspect - what I would like to see.

I believe the Voice-Track Repeater Controller (QST June & July 95) is a example of what QST MPU-based 'construction' articles (product reviews are a different matter) should be like. Preprogrammed EPROMs, disks with the source code and and PCBs are available from the author at a reasonable cost. The code is also available from the ARRL as are the PCB templates. The code is free for personal, non-commercial use. Similar comments apply to the Talking Morse Code Practice Computer (QST July 94).

Bravo to these authors for sharing their work with their amateur friends! I would bet that most people who construct these will likely buy parts from the authors anyway despite the availability of the code - $15-20 for the pre-programmed EPROM is not a bad deal. And, kits are a great convenience for those of us in the boonies. The experimenters among us still have the opportunity fiddle the code and blow EPROMs if they wish.

How would I like things to be - ideally?

1) Take a specific project for a specific MPU (e.g. keyer with memory)

2) Make available algorithms as well as source code to aid understanding and to aid transfer to another MPU or modified hardware platform.

3) Write modularized code/algorithms so that one can more easily add/subtract features that one wants (You do want a programmed practice mode? You don't? OK- your choice!)

4) Post everything on the ARRL BBS for free distribution for non-commercial use and modification (heck, some people might even allow commercial use!)

So, anybody out there willing to write public domain code for something like a simple keyer with memory, a more deluxe keyer, a Morse code 'de-coder' (as in a recent 73 Am Rad article) or even a keyer plus decoder plus digital freq display for QRP rigs? Who knows what someone might develop!

Anyway, I can't 'put up' the code because I am not (at this point) a programmer so I will do my best to 'shut up' on further discussion - but no promises!

3368. Dentron tuner (instruction / pay too much?)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-03 00:00:00 UTC
From: dan drumm <drumm>
Message-ID: <3vrine$q44@koala.uwec.edu>
Source record: 111527
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.amateur.homebrew

I bought a Dentron (model <something> jr.) antenna tuner for $30.00 US.
at a hamfest. Did I pay too much?

I was going to use it with a heath HW100, -- now I know I also need
an swr meter. oops, here comes yet another purchase. Nevertheless,
I would gratefully pay cost + postage + thank-you-very-very-much for
the photocoppied manual.

Other than that, I would like to just get a quick overview on how to
get up and running with the thing. It has one meter, and two knobs:
(and no instructions):

#1 transmitter match a,b,c,d,e,f... switch.
#2 antenna match variable.

The back has tx in, ant out, ballenced out, and unballenced out.

any help greatly appreciated. If you have the manual, please contact me
at drumm@uwec.edu.

Thanks!

Dan Drumm
N9VOX

Wishing you an extra hour each day!

Hi Dan,
If that is the tuner I am thinking about, it has a meter on the front which indicates relative power (with a pot on the back to adjust sensitivity.
I have used the Dentron tuners for several years (both the Jr. Tuner and the much larger MT-2000A. I haven't had one bit of problems with them.
To operate the tuner, you set the bandswitch and then adjust both the transmitter and antenna capacitors for the best match. You can get a rough idea by adjusting for maximum background receiver noise. The settings will obviously change depending on the antenna you are using. The only rule of thumb is the lower the letter setting on the bandswitch, the more inductor you are switching in and the lower the operating frequency.

The is a post on the back for the single wire antenna to which you would hook a long wire or random wire antenna. If you are using balanced feedline, you would put a jumper between the single wire post and one post of the balanced output. There should be a dotted line on the back indicating where this jumper should be placed. In addition, if you are using the tuner on low frequencies and have a hard time matching the antenna, you may want to put this jumper in as the addition of the balun in the circuit will help tune low frequency long wires.
If you will verifiy you have the Jr. Monitor tuner, I have the manual and can copy it for you. You can send me E-mail with an address.

Surplus stores, Herb, surplus stores. I have bought small bags of
large ferrite potting bobbins at surplus stores here in Houston at
prices from .25 to 1.25 each. Probably 10 cents on the dollar or
better. Then I put a small loop in the power cord or computer cable
and push it over the core of the bobbin. I may tape a ferrite bar over
the open end. Works fairly well. If you don't have a good selection
in a local electronics surplus store, buy a couple of electronic
hobbyist magazines and check the adds for the mail order surplus stores
such as Allright and All Electronics etc., etc...

From: dick@netcom.com
Message-ID: <dickDCpwuq.I2E@netcom.com>
Source record: 111531

Here is a simple C program I threw together a few years back to save me the trouble of iterative calculations on a hand calculator. What else is a computer good for? I also bemoan the fact that very few programs are posted for the unix environment, so here is a little contribution. I hope this saves at least one coil-winder a little time...

```
/*

A simple coil calculation program based on the inductance formula
presented in the ARRL Handbook for many years. Artlessly coded by
Dick Arnold, W5VEC.

This program was written on a Sun workstation and compiles and runs
on SunOS 3.5 thru 4.1.3. Hopefully Solaris as well.

Close-wound single-layer coil calculation. To use, simply compile and
run. It's interactive, asking for wire gage if known, and target
inductance. It overshoots the target by one turn. You can fix this if
you want (what's a turn between friends?).

Totally standard disclaimers: not to be used in life-support systems,
military or other applications where loss of life may be incurred.
Change at will; don't ask for help -- I left customer support some
time ago...

*/

#include <stdio.h>

FILE *wfd;

char wfile[80] = {"coil.tmp"}; /* don't ya just hate hard coded stuff? */

main()

{
float dia, tgt, len;
float r,n,l;
int nmax, gauge, eflag;

/* get the variables */

eflag = 0;
printf("\nCoil Calculation Program\n\n");

Couple of points more...
1. The dipper can function as a rather rough super-regenerative receiver
using that audio output (there's no regen control - I did write "rough" :)
2. On my dipper at least, the frequency calibration changes slightly
between used powered, as an oscillator, and un-powered, as an absorption
wavemeter. The scale is calibrated as an oscillator.

But I still reckon they're an excellent thing to have around: not the
last word in accuracy (tune up your unknown circuit with the dipper
oscillating, then bring in the dipper on your main receiver to measure
the frequency exactly), but you can do a great deal with them, and they're
cheap. A lot of "bang for your buck".

Source record: 111533

I guess I have a hard time seeing the difference between a construction article that specs a Curtis keyer chip and one that specs a preprogrammed microcontroller. You have to buy it from a single source and you don't get to know what goes into that one part of the project. I don't see that as invalidating the actual constuction involved or make the article less "pure" than any other.

So the guy who makes the chip tells you how to use it. Big deal. We should be so unlucky as to have the makers of other devices provide simple projects that use them. What if Motorolla were to slip in an article on how to use their power transistors? Or if TI were to sneak in an easy DSP project? WHAT A NIGHTMARE! We Gotta stop this! We gotta write to our Drictors and ARRL HQ and prevent this!

On the other hand, if I developed the code for a project like this, I wouldn't publish it either. Not just for the millions and billions of dollars I'd make selling the part to helpless little hams, but because then I'd be limiting the complexity of the project and thus the support problems.

Stop those useful articles now!

When designing your power supply you must consider power dissipation
requirements. Voltage regulator ICs are quite easy to use,
but you must consider voltage and current AND power dissipation limits.

For your requirements (4-40 VDC at 2 amps), suppose that the
voltage input to the regulator is 42 volts. Then the worst case
for power dissipation is (42 - 4) * 2 = 76 watts. That is a lot
of power to dissipate in a TO-3 case and will require a large heat
sink. I don't have my databooks here, so I am not sure that many
regulator ICs can even handle that much power.

Many regulator ICs are capable of shutting down in case of thermal
overload, but external pass transistors aren't that smart.

>
>Many regulator ICs are capable of shutting down in case of thermal
>overload, but external pass transistors aren't that smart.

If a wide range is desired, the series regulator dissipation problem is
often solved by making the input voltage to the regulator change according
to the aproximate output desired. This is most often done by changing taps
on the 60Hz transformer that feeds the rectifier/filter at the input to the
regulator section. The supply would then have at least two ranges: "high",
which applies about 42V to the input of the regulator, and "low" using
about 21V. The switch that selects the transformer tap would also select
part of the feedback resistor so the output voltage is only adjustable to
values apropriate for that range (4-19V Low, 19-40V High). Automatic
selection could also be implemented, using a relay and a voltage comparator
on the output. This has the additional advantage of returning to "low"
input when the output is overloaded.

Worst case dissipation would occur when the lowest setting of the high
range is used, for example 19V. Then you have 2*(42-19) = 46W, which is a
considerable improvement, and probably low enough to use the regulator
alone with a good heat sink but with no need for a pass transistor. In
case of a shorted output on the high range, the regulator could overheat,
but its internal protection would prevent damage.

3377. Optoisolator cross-reference help and PAL programming information

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-03 00:00:00 UTC
From: negaard@draagen.graceland.edu
Message-ID: <NEGAARD.95Aug3122626@draagen.graceland.edu>
Source record: 111536

I'm working on building the OptoSCC card designed by Henk Penk, PA0HZP, and intended for use with a variety of digital-mode modems. I've got the schematic, and I've located all the parts I need except for the optoisolator chip. It's specified in the bill of materials as a PC847, and I can't find this chip or an equivalent. I've e-mailed PA0HZP, but he may not be able to respond for any of a variety of reasons, so I'll try here. Can anyone help?

The other part of the project that's missing is the PAL used to decode the PC bus logic. It's a 20L10 and I can get the part, but I don't know how to program it. Maybe I'm confused, but one must program Programmable Array Logic, mustn't one?

I expect that I could figure what the program ought to be, given enough time and energy, but I thought I'd pursue a solution with those wiser, first (I hope you're all wiser than me, else the state of homebrew may be serious ;->=).

Is there any help available for me out there?

From: tomb@lsid.hp.com
Message-ID: <DCr0Mu.uF@hpcvsnz.cv.hp.com>
Source record: 111539

Thanks to Richard Arnold for posting the c program to help figure coil winding info. I noted he used a case statement to access tabular wire info. Here are a couple formulas that folk might find useful to calculate wire diameter and approximate resistance in ohms per 1000 feet at 20C, as an alternative to entering a table.

The diameter formula is accurate to better than 0.1% (I doubt that manufacturing tolerances are ever this good), and the resistance error, a couple percent max for gauges from 0 to 30 or so, is about the same as a 5 degree C change in temperature (and it's almost dead on at 12 gauge), so should be fine for practical work.

d = 10^(-.05035*g - 0.4884)

r1000 = 10^(0.1*g - 1)

where

d = wire diameter in inches

r1000 = resistance of 1000 feet of wire at 20C, in ohms

g = AWG gauge number, from 0 to 40. You can substitute -1 for 00, -2 for 000, etc., to extend to even larger diameters. (I guess they might even be fine for gauges finer than 40, but the table in front of me doesn't go that fine.)

(It always amazes me how simple the constants in the R1000 formula are!)

3382. August QST construction article wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-03 00:00:00 UTC
From: raateland@vyh.fi
Message-ID: <1995Aug3.221424@vyh.fi>
Source record: 111541

So there is all this commotion about a construction article in the August 1995 issue of QST that wasn't a construction article, but read this:

I don't get QST, but today I received an IDIOM Press Super CMOS Keyer III that I ordered after I read about it on the QRP-L list. Guess what, the Tutorial/Operating manual refers to 'the construction article', but all that is included in the manual is the schematic, no details about construction.

Well, having some experience with these kind of things, I don't expect much difficulty in putting the thing together, but if anybody has actually read the 'construction article' and found interesting details that would be good to be aware of before connecting the PC-board to anything else, I would very much like to know. I'm also interested to know what there is in the QST article about the workings of the keyer.

I have the 1994 ARRL Handbook, wherein there is a description (construction article?) of the CMOS Super Keyer II.

The local public library doesn't have QST, so I can't have a look at the article myself.

Actually, the answer is 170-190KHz, maximum of 1W PA input, 15m
total length of antenna, feedline and grounding system.

>The saving thing was that you have no restrictions on the receiving
>ant.. Make it BIG :)

Or make it an active loop...

********** TKC **********

My recent poking around the Internet has let me to conclude that 1750 meters
is governed by Part 15:

Sec. 15.217 Operation in the band 160-190 kHz.

(a) The total input power to the final radio frequency stage
(exclusive of filament or heater power) shall not exceed one watt.
(b) The total length of the transmission line, antenna, and
ground lead (if used) shall not exceed 15 meters.
(c) All emissions below 160 kHz or above 190 kHz shall be
attenuated at least 20 dB below the level of the unmodulated
carrier. Determination of compliance with the 20 dB attenuation
specification may be based on measurements at the intentional
radiator's antenna output terminal unless the intentional radiator
uses a permanently attached antenna, in which case compliance shall
be demonstrated by measuring the radiated emissions.

and that experimenters like ourselves are governed by:

Sec. 15.23 Home-built devices.

(a) Equipment authorization is not required for devices that are
not marketed, are not constructed from a kit, and are built in
quantities of five or less for personal use.
(b) It is recognized that the individual builder of home-built
equipment may not possess the means to perform the measurements for
determining compliance with the regulations. In this case, the

builder is expected to employ good engineering practices to meet
the specified technical standards to the greatest extent
practicable. The provisions of Sec. 15.5 apply to this equipment.

and the relevant part of that section reads:

Sec. 15.5 General conditions of operation.
...
(b) Operation of an intentional, unintentional, or incidental
radiator is subject to the conditions that no harmful interference
is caused and that interference must be accepted that may be caused
by the operation of an authorized radio station, by another
intentional or unintentional radiator, by industrial, scientific
and medical (ISM) equipment, or by an incidental radiator.
(c) The operator of a radio frequency device shall be required to
cease operating the device upon notification by a Commission
representative that the device is causing harmful interference.
Operation shall not resume until the condition causing the harmful
interference has been corrected.
...

According to Part 15, we are talking about intentional radiators, and
of course, you want to cease operating before 15.5(c) applies. Note also
that Part 15 doesn't talk about receiving antennas; that's a matter
between you and your local zoning authority...

Please see:

ftp://ftp.cs.buffalo.edu/pub/ham-radio/1750m.band

for further details, including an organization and journal for the 'lowfer'.

Part 15 is available from The U.S. House of Representatives Internet Law
Library Code of Federal Regulations [http://www.pls.com:8001/his/cfr.html
ask if you need help searching it].
-- KD6PAG

P.S. I'd be interested in hearing from any S.F. Bay Area lowfer's, if
there are any around who might help me get started. Anyone know which
issue of "73" or "QST" had the 'lowfer' project in the past few years?
I misplaced my copy.

I run an NTP client on my pc (a clonebox 486), and as a result its clock is accurate to about +- 25 milliseconds at all times. That's one of the joys of running a un*x and having a PPP link to the internet :). See comp.protocols.time.ntp for more info. Without the NTP client, the pc gains two or three minutes a month and drifts wildly with temperature.

>to unit.

There must be a lot of variation; an MFJ here loses about 12 to 13 seconds a month, while a $20 timex watch (which has a 24 hour display format option) is only 50 seconds slow after two years.

Why go to all this trouble, and then have to pay to update your clock?
Last time I checked CHU (the Canadian version of WWV) output a data burst
every minute or so for just this purpose.

There was a project designed some time ago with receiver, decoder, and
software for updating a machine running un*x. Last that I checked the
schematics/instructions/etc were available on the local ham fileserver
hydra.carleton.ca, somewhere in the anonymous ftp section. I haven't
built this thing yet, so I can't comment on how well it works.

regards,
Dean.

Hey! None of that obscenity here! This is r.RADIO.a.h. If you're going to discuss such topics be so kind as to include a RADIO in the project. :-)

On the other hand, a notoriously cheap ham (aren't we all?) with internet access PAYS $0.15/week to set a clock when it can be done quite nicely over the net? For "free"?

73,

Here's another project idea.

I, like thousands of other hams, have one of those cheap MFJ dual clocks that never seems to be able to keep the correct time. Plus, I'm tired of having to reset it all the time.

My idea is a clock that runs by itself, but gets its time set via the serial or parallel port of a PC. Perhaps the clock would reset itself to the computer time when the PC is first turned on and then once a day for those that leave their computer on all the time.

Some might argue that the clock in a PC is notoriously innaccurate. While this is certainly true, there are several shareware programs available that will set the PC clock to WWV or the naval observatory via modem. I use one such program about once a week. The call costs about fifteen cents.

The clock would have dual (12 hour local/24 hour UTC) displays (LCD).

Anyone want to take up the challenge??

: Anthony G. Catalano WW2W

No, this is a discussion group, and it would be considered rude,
especially since a large number of the people reading the group have to
pay for every byte that passes through their modems.

The generally approved method is to place the files on a public
FTP site, and post a notice in the relevant group as to its
availability.

Thank you, however, for asking. A lot of people wouldn't have gone to
the trouble. :-)

From: jefman@interlog.com
Message-ID: <3vsst0$1dl@gold.interlog.com>
Source record: 111557

Hi - has anyone built an interface to control a Macintosh computer through touch-tones? I want to be able to control a hypercard program remotely.

Ideally it would work in software; I'd send the audio into the microphone input an analyse the tones. I have a program for the Mac that does this, but I can't access the data from it. It just prints the numbers to the screen. I've tried to contact the author, but no luck so far... btw, I'm using an AV mac which has a DSP chip built-in.

Most likely I'll have to build a black box with a DTMF decoder chip in it, and send the output through the serial port. If anyone has done this, particularly to control Hypercard, I'd appreciate any advice. Thanks.

Hi:
I have got a broken DC power supply, whose only problem
seems to be a blown BUZ 332A power FET transistor.
I tried to either buy such a transistor, or to find a replacement,
but weird enough I cannot find it in any catalog. I even asked
my friend in Europe to check it for me, but he could find
only BUZ 330 and BUZ 331. So, my questions are:

1. is there any US mail-order source, which would offer BUZ 332A?
2. what is the replacement for BUZ 332A (close replacement) ?
3. anybody knows the specs of BUZ 332A?

Please e-mail to skulski@nsrl.rochester.edu

Excuse me for taking bandwidth in this newsgroup. I could not
locate any other newsgroup dealing with electronic parts, this
one seemed to be the closest I could find.

Thank you in advance for info.

From: steve6920@aol.com (Steve6920)
Subject: Re: Dentron tuner (instruction / pay too much

Hi Dan,
If that is the tuner I am thinking about, it has a meter on the front
which indicates relative power (with a pot on the back to adjust
sensitivity.
I have used the Dentron tuners for several years (both the Jr. Tuner and
the much larger MT-2000A. I haven't had one bit of problems with them.
To operate the tuner, you set the bandswitch and then adjust both the
transmitter and antenna capacitors for the best match. You can get a
rough idea by adjusting for maximum background receiver noise. The
settings will obviously change depending on the antenna you are using.
The only rule of thumb is the lower the letter setting on the bandswitch,
the more inductor you are switching in and the lower the operating
frequency.

The is a post on the back for the single wire antenna to which you would
hook a long wire or random wire antenna. If you are using balanced
feedline, you would put a jumper between the single wire post and one post
of the balanced output. There should be a dotted line on the back
indicating where this jumper should be placed. In addition, if you are
using the tuner on low frequencies and have a hard time matching the
antenna, you may want to put this jumper in as the addition of the balun
in the circuit will help tune low frequency long wires.
If you will verifiy you have the Jr. Monitor tuner, I have the manual
and can copy it for you. You can send me E-mail with an address.

A good program to check out is Time Set availible on the Rancho Palo Verde
bbs. I can't get to the number right now but e-mail me and I'll have it.
The program dials NIST or the Naval Observatory. This is well done but
not unusual. It also provides a sync pulse on one pin of the parallel port to allow
other devices to be linked.
I never realized the MFJ was so bad. I bought the Radio Shack 1-1/2" face
digital clock, with 12/24 hour format. Easy to read, but bulky. I reset it about twice
a year. Of course it may vary from unit to unit.

Why use the PC at all then? Build a modem into the clock! The Motorola MC 145444 (unfortunately listed for about $8 - $12, but still cheaper than a PC and modem) includes a DTMF dialer and a 300 baud modem. The chip uses 8 mA at 5V while active and can be shut down when not. Other companies make similar chips for "call-home" applications like this. There is a wide market for them considering devices like credit-card verifiers, utility meters, etc. You would probably need a relay/transformer to couple to the phone line, and likely some sort of FCC approval on the whole system.

Then the clock's serial port would be an *output* of accurate time, which the PC could obtain from the clock any time it needs to, without incurring any phone cost. Also the clock could be taken anywhere, plugged into a phone line, and set itself without needing any other hardware. The reset process could occur on a weekly or monthly schedule, or when the user requests it by pressing a button on the clock.

Another option would be to equip the clock with a serial port intended for input of the correct time from the PC as described, but also include in the clock's software a protocol to drive an external modem (such as an old Hayes Smartmodem 1200) to call in and get the time. Then you have clock+modem, rather than clock+modem+PC+software to do the same thing.

So many choices...

From: ai557@ccn.cs.dal.ca
Message-ID: <DCsxG2.IAB@cs.dal.ca>
Source record: 111569

Hi!
Some have been asking how to post schematics on the newsgroup.
One of my previous jobs was entering BDL files into an old Automatic
In-circuit Tester (Factron 770). BDL is Board Description Language.
Part one of each file is a parts list. Part two is a "net
list". Example (small part anyway!):

"VCC" IC1.14 IC2.16 C1.AN C2.AN J1.PLUS
"GND" IC1.7 IC2.8 C1.CA C2.CA J1.MINUS

The format is basically: "nodename" connections...

Needless to say, a '486 motherboard would live up to its name...
We sometimes called it _Bored_ Description Language (hi).

>Well Murray,
Do you expect the cable manufacturers to be :
>Should they "know" what frequency your going to use their cable for?
>Should they "know" what length to make your cable?
>Should they "know" what power level your going to use?
>Should they "know" what attenuation you consider adequate?

>The torroid materials have a frequency range!
>They have a finite power handling ability/volume!
>They have finite attenuation characteristics.

>Enough?

>Tom

Tom and Murray,

That is very true. The problem of power handling can be simplified to the voltage across each bead and the heating of the bead at that voltage on that frequency. For example, one popular string of beads balun has an equivilent parallel impedance of 1500 ohms R in parallel with 1500 ohms XL.

The resistance dissipates power, and while that balun may handle 1500 watts with a balanced 50 ohm termination, it certainly won't handle much power with a 500 ohm load or any antenna that has high voltage from the terminals to ground.

I've found that if space is available it is much cheaper to use an air wound balun than beads, and the power handling and choking impedance can be made higher.

Roy Lewallan posted some nice impedance data on baluns last month. It was good stuff.

Tom sure said it. Too many applications with too many variables involved for one fits all product.

73 Tom

3416. NEW HAM RADIO REMOTE CONTROL PRODUCT OFFERED

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-05 00:00:00 UTC
From: Marshall Craw <mcraw@halcyon.com>

I am pleased to announce a new product offered by Positive Time Systems called the RCS-I. This is a radio controller that connects to any VHF/UHF transceiver and can issue x-10 commands. (X-10 is a power line standard for controlling devices throughout a building. Sears, Radio Shack, and others offer these compatible units)
The unit also has an alarm input, a listen feature, a short voicmail box, and responds to all commands in a pleasant female voice. The system IDs with your recorded voice and call sign. This description doesn't do the product justice, so please check out the new homepage at :

http://www.halcyon.com/pos.time.sys/top

or you may email us with you address so that we can promptly send you our brochure and newsletter.

NOTE: This product is intended for US voltages of 120 / 220 VAC. Another version will be offered to support other international power standards. Email for more information.

Thank You,

Marshall Craw <mcraw@halcyon.com>
Positive Time Systems

---
I don't care what THAT book said. It was either a misprint or a typo on
your part....
because I respectfully must imform all that the limit of the combined
feedline and antenna
system for transmitting can only be a maximum of 15 (fifteen) feet.
If you live near salt water, use it as a ground and place the x-mitter
directly at
the base of the antenna. The vertical portion would then be 15 feet (
constructed with a copper ribbon/tubing or multi-wire to compensate for
R-loss) with a large capacity hat to bring the resonance down as far as
possible without having the outer perimeter of the capacity hat fall below
20% of the vertical portion of the antennas' vertical mast
Out of the 1 watt input to the antenna, consider yourself lucky if 50
milliwatts remain as the radiated portion. A cold winter night is the best
time to recieve VLF signals because of the few static crashes.
I remember reading about a small identifying paper having to be affixed
to the transmitter
with pertinent information on it. I will try to find the article/book that
I had read that from.
If ANYONE get a VLF transmitter on the air or would like to post a list of
vlf xmitters
that you can hear well please post it here. I'm sure 99.999 percent of that
stuff is homebrew.
It is also interesting that you literally can make up your own callsign/id
on there (trying not to duplicate an existing one) If you are allready a
ham you can use your call as it is very unlikely
that it is allready being used on vlf! Most IDs are 3 letters in lenght in
the entire vlf band.
A good idea for a vlf keyer would be a keyer that IDs with a qso number
that changes
every day so you can be sure that qsl report is a genuine one and get a
good picture of propagation...
I have also noticed that the vlf signals are all continuous AM keyed with
the identifying audio.

>
>And presumably small tuning steps would be a necessity.
First, yes but it would only be "clarified" if the original suppresed
carrier
frequency (converted) were to be adjusted to fall in the middle of the IF
to match
the fixed BFO frequency as your example gives.
By "as long as there are no othere signals" I mean it would still work, but
a
signal on "the other side" would not be selectively attenuated against
the desired signal in any way unless the shaping of such an IF filter were
offset
to favor one of the sidebands.
A direct-conversion receiver works EXACTLY as YOU have described above
except that there is no frequency conversion performed, although
technically
speaking the first "IF" is the AUDIO produced! (as you can imagine a fixed

bfo in a direct conversion receiver can become very boring feature- Ok for
WWV rec'pt.)

oops forgot to answer that one...
Sure, small tuning steps would be peachy-keen to have.
however it has nothing to do mathematically/electronically
with the radio being able to detect signals or not.
(to receive them well/correctly, yes-- I am nit-picking to make a point
only))
If a commercial SSB or AM station is X-mitting exactly on 11005khz
and you can tune in 1khz increments (on SSB mode) and your in luck.
If a ham is on 7.180.5 the closest you can get to his/her frequency
would be 500hz. In THAT case 100hz tuning resolution WOULD
be a very desirable feature in order to zero-beat that signal and
recover it's original intelligence. In my opinion 100hz resolution for a
digital
receiver in ssb mode should be the highest minimum resolution acceptable.

If you can, use power PNP transistors as the pass devices because using NPNs as pass
transistor place the load between from the emitter and ground. (affecting regulation)
The PNP configuration puts the load between the positive supply and the collector.
The collector, unlike the base and the emitter is the only non-controlling electrode
on a 3 leg xsistor.
(actually the same can be done with an NPN by reversing a few things and using an
positive groung isolated from the cabinet but its too confusing a project for a beginner)
Look for a schematic that uses a good reference source, not just a zener diode.
Reference groung at ONE common point: loops or ground voltage differences can
become significant in high-current power supplies.
At 20 amps use 4 pass transistors as a minimum to run cool and also use equalizing
resistors (.05 to .15ohms ??) at the output leg of each one in order to avoid just
one from "hogging" all the current, creating a hot-spot within that transistor.
Any regulated power supply for RF should us a METAL cabinet and the leads should be
RF-shorted to ground using a few capacitors (.01 .47 and a 1uf from positive to the
metal cabinet just befor exiting. The negative line may allready be directyl connected
to ground in most cases so bypassing won't be needed.
Fuse the 110 in and the 12v out!!!
If possible include an overvoltage circuit to protect your fed equipment from cooking. (a simple "crowbar" circuit.)
Meter, meter... use a meter.
Have fun & stay away from 3,000 volt B+ supply projects for now.

Thanks, Tom Sefranek, for your reply. Obviously there is some
confusion here, as we are talking apples and oranges. My fault
for not explaining further perhaps?

Just as old TV frame transformer ferrites are used for current
baluns at RF even tho their resonant frequency is at 15KHz the
resonance of EMI suppresive ferrites is mostly 'the lower, the
better'. The technique already exists. There are RF suppressive
computer cables available already and the extension to Coax is
logical.

The use of toroids is a poor solution really. The radius of the
toroids have a direct relationship to the effectiveness of RF
control. Halving the radius doubles the effect and to put ferrite
right up on the outside skin ia as close as one can get.

The other factor in toroids is the hight. In putting some ferrite in the plastic
the height is as long as the feeder. Not just the last 2 feet.
This would also have the benefit of increasing the surface area
to allow for heat disipation under total mismatch.

The need to go down from half inch to 1/4 inch coax to wind thru
a frame or toroid would be removed and the heating of its dielectric
and subsequent 'walking' of the center conductor removed. The feeder
could be half inch all the way with no expensive toroids to buy/fit.

To summarise:
The frequency range would be all RF but the higher freqs. would
be removed first.
Power handling should be high with an 'average' run of say, 10 m.
How much is 'enough'? Some is always better than none!
I would just like to see RF suppression at HF and VHF of legal
amateur powers for what should be a marginally more expensive
coax than we buy at the moment. The ferrite powder is cheap.
I know. I bought some. It is made for just this purpose - RF
suppresion on PC cables.

Think about it. And thanks for the come back.
Murray Kelly. vk4aok.

>for a beginner)

Although using a common-emitter configuration for the pass transistor has some advantages, the main disadvantage is lower stability. The common-collector configuration (load connected to emitter) has inherent negative feedback which prevents the emitter voltage from varying widely while the base voltage is held constant. (The fact that the emittter is a "controlling leg" is an advantage since it controls in a manner that will stabilize the output voltage). Common-emitter circuits act more like current sources, which makes it more difficult to stabilize the output voltage. Additionally the often low ft of power PNP transistors can complicate the stability problem. Another advantage of the common-collector is that the drive current also flows into the load, rather than needing to be dissipated in the driver.

>Look for a schematic that uses a good reference source, not just a zener
>diode.

Absolute laboratory precision of the output voltage is not required for battery replacement type applications, since the equipment being powered is built to handle varying battery voltages. What is important is low ripple from the reference source, since this ripple will appear at the output as well. A Zener diode with two capacitors in parallel with it (one small, to catch RF, and one large, to stop 60 Hz) will do this job nicely. Most commercial supplies are built around the 723 type IC, which includes the reference voltage generator for you.

>Reference groung at ONE common point: loops or ground voltage differences
>can
>become significant in high-current power supplies.

Absolutely.

>At 20 amps use 4 pass transistors as a minimum to run cool and also use
>equalizing
>resistors (.05 to .15ohms ??) at the output leg of each one in order to
^^^^^^^^^^
Should say "emitter" here, regardless of which lead is the output of the
amplifier.

>avoid just
>one from "hogging" all the current, creating a hot-spot within that
>transistor.

The equalizing resistors need to be in the emitter and/or base leads in any
case to absorb differences in the Vbe of the transistors. The collector,
being a current source, will not be affected by a small resistor in series.
If power MOSFETS are used instead (generally more expensive), then no
resistors will be required, they are voltage-driven and can simply be
connected in parallel.

>Any regulated power supply for RF should us a METAL cabinet and the leads
>should be
>RF-shorted to ground using a few capacitors (.01 .47 and a 1uf from
>positive to the
>metal cabinet just befor exiting. The negative line may allready be
>directyl connected
>to ground in most cases so bypassing won't be needed.

Another important point. Using the point where the negative lead leaves
the cabinet as the single point ground would make sense too. Using a
capacitor of several hundred uF on the output will also make the
regulator's job easier in regard to transients, and may even be required to
keep the regulator stable into all loads.

>Fuse the 110 in and the 12v out!!!

Definitely need a fuse on the 120V in. This is the only place that really
needs a fuse since the power supply doesn't generate power, it just
transforms it. The 12V out will have a current limiter of some sort, and
if that fails, the input fuse will blow if it is sized properly.

>If possible include an overvoltage circuit to protect your fed equipment
>from cooking. (a simple "crowbar" circuit.)

Remember to RF-bypass the triger circuit for the crowbar to prevent it from
acting unnecessarily when there is RF around. And never connect a supply
equipped with a crowbar directly to a lead-acid battery without a fuse (a
blocking diode will keep the fuse from blowing, but isn't essential for
safety). Come to think of it, of course never connect ANYTHING to a
lead-acid battery without a fuse right at the battery.

>Meter, meter... use a meter.
>Have fun & stay away from 3,000 volt B+ supply projects for now.

In general, commercially-built linear power supplies (in the 5 Amp and up
class) use NPN transistors as the pass element, controlled by a 723 and

driven by a smaller NPN transistor. The driver circuit is powered by higher voltage from another winding on the transformer or (in smaller supplies) a center-tapped rectifier arrangement. With boosted drive voltage readily available, the main advantage of the common-emitter pass circuit, low dropout voltage, is not a factor, since the common-collector stage can be driven to saturation.

Another trick, rather than dropping 0.7V at the full output current to sense for overcurrent, is to monitor the base drive current instead, since the gain of the output transistors is roughly known, a current limiter adequate for protective purposes anyway can be realized without needing a 50W low-ohm resistor.

For low-current power supplies (1-5 A, for less than 1A just use a 3-terminal regulator), discrete transistor regulators are practical. Usually the error amplifier is implemented with a NPN transistor with the emitter connected to the reference and the base connected to a voltage divider. The reference is a Zener diode, or one really popular design used the front-panel pilot light LED as the reference! Not recommended unless cost is a real concern. The collector of the error amplifier transistor drives a driver transistor, then the output transistor. Both of these are common-collector. It is also quite feasible to use a 3-terminal regulator to drive a current booster transistor for the 1-5A class, but the current limiter for this design requires another medium-power transistor, and the dropout voltage can be quite high as well. The Radio Shack 2A supply (copying not recommended), actually uses a 15V Zener driving two common-collector stages with no feedback other than that inherent in the voltage followers. It doesn't work very well, but shows what can be gotten away with.

1 foot = 0.3048 meter (or 1 meter = 3.28 feet) So 15 meters is 49.2 feet,
which matches reasonably well with "50 feet" quoted in other sources.

How about a 49 foot cube of ferrite, with several turns of heavy copper
ribbon around it, then tuned to resonance with a BFC? Or does the
regulation permit only vertical antennas, no loops?

>hmmmm this just gets curioser and curiouser....
>Anthony Catalano WW2W

I'd like to learn more as well. Is the Part 15 you quoted on-line
somewhere, or will I have to walk 3 blocks to the library and read it from
paper?

Well,
What step-down transformer do you have? (Voltage and current)
That the FIRST place to start.
If you don't have a transformer, or want to size it before building/buying,
Assume you mean 13.6 Volts out,
Plus 3 volt loss in regulator burden,
Plus 1.5 volts rectifier burden,
You need a transformer with about 18 VRMS at the current you desire, or more.
Quick rule of thumb, for the capacitor is 1,000 mfd for every amp.
so about 20,000 mfd at 25 VDC minimum.
There are so many good choices for linear regulators and pass transistors,
DON'T use the tired multiple 2N3055 design unless it's the only transistors
you can get.
Power FET's rule!

Feel free to E-Mail me for further advice.

Where did you get this restriction? You'd better get the
Code of Federal Regulations updated, too, since it also contains
the same "misprint".

Just so you can check on this, have a look at Title 47 of the
Code of Federal Regulations, Part 15.

You aren't allowed to a callsign which has been or could be issued
by the FCC, such as an amateur callsign. Maybe you'd better that
mistake in Part 15 fixed, also.

>Enjoy. Anthony G. Catalano WW2W //"nothing is foolproof because fools are

3442. VFO Stability

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-06 00:00:00 UTC
From: rohrwerk@netcom.com
Message-ID: <rohrwerkDCwv2K.LB5@netcom.com>
Source record: 111451

I'm pretty finicky about VFO drift, being a musician with acute sensitivity to pitch. So I thought I'd share a few experiences in homebrewing 7 MHz VFO's and ask some other comments/advice.

The simple Hartley circuit (such as W7EL's Optimized QRP Xcvr) never satisfied me -- it never seemed to settle down, with a slow drift downward that never stopped. This is after boiling the toroid (which helped), and using NP0 caps. It went down about 200 Hz in an hour (cold start), thereafter about 80 Hz per hour -- enough to notice during a QSO, because at 750 Hz a change in pitch by a half-step (musically speaking) is about 40 Hz -- noticeable to me! This is after boxing it up carefully, letting it cool a long time, etc.

Incidentally, it's interesting to listen for drift when heating the leads of individual components. A quick probe with the iron, and withdrawing a safe distance, showed that capacitors marked NP0 do indeed have *some* drift in an imperfect world, but most of them moved very little (and in either direction!) Heating the transistor, and even the RIT tuning diode, had less effect than I thought. BUt, of course, the TOROID was the biggest culprit, providing a siginificant downward drift of 1 or 2 kHz (i.e., more inductance) when the iron was stuck in the hole for about 2 seconds. (This is a T-44-6 coil).

Substituting air wound Miniductor stock helped, but again that steady drift down.

Then I built up the series-tuned Colpitts used by W1FB, a breadboard version without a box. At 7 MHz, a toroid inductor (about 6 uH) again proved unsatisfactory, the drift being about the same. Using a piece of close spaced airwound coil stock, stability improved a lot, with many 1 hour periods where I could leave the room and return, and the pitch remained steady to my ear. (this means less than 40 Hz).

Better yet, a close-wound wire coil on a 1/2 inch ceramic form (no slug) did even better in the above circuit. One run I left it sitting all night, and it stayed with a half-step at about 200 Hz audible pitch -- a drift of about 10 Hz! Spot checks during the day show&#65533;d it staying within about this range. Other runs varied, but were significantly better than other configurations. And all this without a box, though in a room without windows with fairly steady temperature (when the central air isn't on).

Both of the air-wound coils were far more immune to drift from blowing on them at a distance (warm air from your breath).

My drift was measu&#65533;ed by ear on a RS DX440 receiver, with BFO continually recalibrated to zero beat on 10 MHz WWV. (Yes, you CAN hear zero beat if you listen for variations in background noise, and especially when it's modulated with a continuous tone).

So, it seems that the old Miniductor stock, with its plastic ribs, is pretty good, but prone to some drift from heating. I wonder how good a piece of small PVC pipe would work -- because my ceramic forms are a bit large and I don't know how to cut them cleanly!

This agrees closely with my own experiences building VFOs. One of the most stable I ever produced was built around the older W7ZOI high-stability (JFET) Hartley circuit. I used an ARC-5 transmitter covering the 80M band as a test bed and simply wired the FET, diode and one or two small fixed ceramic caps onto the tube pins of the original oscillator. The caps I added were *not* NPO. For anyone not familiar with these transmitters, their VFOs used a very large ball-bearing tuning cap, an air trimmer, and a large ceramic coil form (about 1-1/2") with heavy gauge wire and a tunable iron slug. All of the tuned components were enclosed in a formed aluminum shield on the top side of the chassis.

Anyway, after installing the circuit in the original chassis, I found that the original dial markings were almost exactly correct, and that only a slight adjustment of the trimmer and slug were required for perfect alignment. Most of the cold start drift occurred in the first 15 minutes and was measured at better than 100 Hz over the first hour, improving to better than 10 Hz per hour thereafter. After confirming this with cold starts on several consecutive days, I let the oscillator run overnight. The <= 10 Hz wanderings recorded during previous runs were both positive and negative, and the final measurement after more than 24 hours was still within 10 Hz of the frequency achieved after one hour of warmup. FWIW, the counter used for these tests had a 10 MHz ovenized oscillator and was adjusted to WWV (as necessary) before each measurement.

There is no question in my mind that ceramic forms and large gauge wire are a significant aid to good VFO design. At the very least, starting with these components can save many hours of cut and try in attempting to build stable VFOs.

3444. Gyrator Curcuit design

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-06 00:00:00 UTC
From: joe@westonia.com
Message-ID: <DCwxuy.41r@westonia.com>
Source record: 111453

I am looking for information on a method of curcuit design call the 'Gyrator'.
What is of interest is that the design uses resistance, rather than
inductance, to create impedance.

What the basic cuircuit looks like is a group of resistors in series of the
same value with one capacitor in that series line.

For an example of a curcuit using 5 resistors, the formula for calculating
inductance would be
L=

R1 R3 R5

R2 1/C1

I've seen some very technical references to this in my searches, but nothing
basic enough to be able to work with.The value of this information would be
for low frequency work (160 and 80 meters).

Thanks in advance

Joe

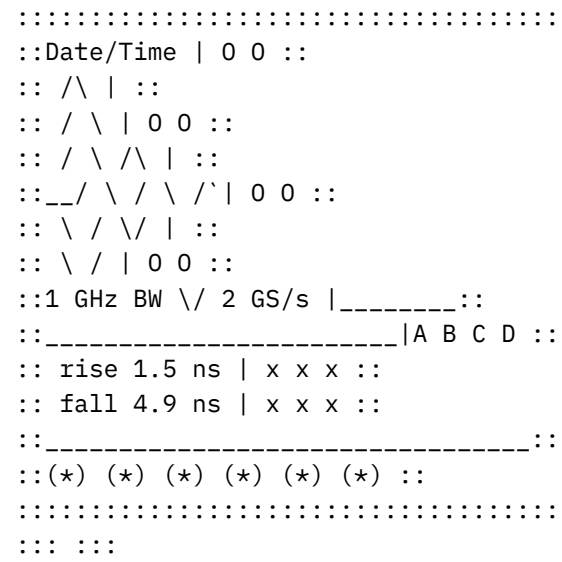
Digital Scope.FAQ - Version 1.09



Dear Technologists:

This Digital Scope.FAQ file contains many (but not all) of your answers to the more "Frequently Asked Questions" re: Digital Storage Oscilloscopes (DSOs).

Key Issues reviewed in this file include:

* DSO INDUSTRY TRENDS (Whats happening in DSO technology in 1995?)
* DSO FORM FACTORS (What types of DSOs are there?)
* PRIMARY DSO FUNCTIONS (What can DSOs actually do?)
* APPLICATIONS (What are the most common DSO applications?)
* ADCs (What speed do I really need on each channel?)
* BANDWIDTH & TRIGGER (What numbers and functions are right?)
* ARCHIVAL & MEMORY (How fast, how deep, and can I get more?)
* DISPLAYS (What am I really looking at?)
* MEASUREMENTS (How much is my signal changing over time?)
* DIGITAL SIGNAL PROCESSING (How can I obtain more useful information?)
* DEMOS & PURCHASING (How can I see and get the DSO I really need?)

Feel free to contact me anytime (john@wd1v.mv.com) if you have additional questions or comments.

*If you want the latest version of this file sent to you automatically, send an EMAIL where the subject field contains the text "subscribe scope.faq".

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

DSO INDUSTRY TRENDS 1995

MORE DSOs ARE NOW SOLD THAN ANALOG SCOPES. Expect most new scope models to be DIGITAL and have faster sampling, higher bandwidths, deeper memories, and lower costs than in 1994. COMPARABLE MODELS HAVE FALLEN IN PRICE BY ABOUT 50% IN THE LAST 4 YEARS. The DSO market is very competitive - thats good news for buyers.

DSOs STILL VARY IN PERFORMANCE IN A VARIETY OF WAYS. Each manufacturer provides a certain degree of standard features, but their different design schemes produce unique performance strengths and weaknesses. Compare and evaluate.

```

SMART CHOOSERS typically let their S I G N A L S determine the primary specifications (Sample Rate, BW, Memory Depth, Trigger BW, etc.) and let their A P P L I C A T I O N determine secondary specifications (I/O, Measurement, DSP, etc.).

MAINFRAME POWER IS NOW IN THE NEWEST PORTABLES. DSOs now can include memory depths > 1M samples per channel and offer processing options such as HISTOGRAMMING or FFTs on up to 6M samples.

DSOs ARE GETTING EXTREMELY COMPUTATION INTENSIVE. Deeper memories, multiple channels, high resolution displays, and enhanced DSP routines tax the fastest CPUs and smartest firmware. Latest designs use multi-processor architectures. SMART CHOOSERS must know the CPU specifications as well as the key DSP benchmarks.

DSOs AREN'T JUST FOR TRANSIENT CAPTURE ANYMORE. Latest DSOs can now process multiple sweeps and generate envelopes, compute statistics, do complex DSP functions, conduct stand-alone tests, archive and print data, and even FAX DSO screens with measurement and test results to/from remote sites.

DSOS ARE BEING OPERATED BY MORE COMPUTERS as redundant tests and measurements are being automated. Most DSOs come with IEEE-488 and RS-232 interfaces and offer remote programmability and data transfer. Most DSOs have free or low cost device drivers for popular software packages.

DSOs ARE THE HIGHEST BW OSCILLOSCOPES AVAILABLE. The highest BW "ANALOG" scope currently in production is only 400 MHz. while several DSOs go well beyond 1 GHz. The future is clearly digital!

MAXIMUM REAL-TIME SAMPLE RATES (Single Shot) can now go to 10 Giga-samples in 1 new portable DSO model just announced.

ACQUISITION MEMORY DEPTHS are expanding from 10 K to 50 K (typical MINIMUMS) and up to 8 Million samples (maximum).

CLOSENESS TO SOURCES IS ALSO GOOD NEWS FOR SMART CHOOSERS. The vast majority of the DSOs that are sold in the United States are manufactured by US Corporations making delivery, service, calibrations, and support most convenient.

UPGRADE PATHS for firmware and hardware expansions are becoming common. but not all models can be upgraded - another issue of concern for SMART CHOOSERS.

DSOs ARE THE PRIMARY DEBUGGING TOOLS FOR HIGH SPEED DIGITAL CIRCUITS since they can now sample so rapidly and trigger on so many different fault conditions.

TRIGGER RATES are becoming an important specification with varying amounts of information per trigger or sweep.

SOME DSO MANUFACTURERS ARE OFFERING COLOR DISPLAY OPTIONS. Some versions utilize the colors cleverly with COLOR GRADED PERSISTENCE.

While many applications only require a single channel DSO, MOST USERS ARE NOW PURCHASING 4 CHANNEL DSOs.

SOME manufacturers can INTERLEAVE the CHANNELS of their DSOs so that, for example, in a 2 channel model, twice the sample rate is achieved when using just 1 channel compared with both channels being used.

SOME manufacturers can INTERLEAVE the MEMORIES of their DSOs so that, for example, in a 2 channel model, twice the memory depth is achieved when using just 1 channel (and twice the recording time) compared with both channels being used.

SOME manufacturers can INTERLEAVE CHANNELS and MEMORIES. *SOME OFFER THIS FEATURE ONLY WITH THEIR DEEPEST MEMORY OPTIONS - be careful.

Functions are increasing so the USER INTERFACE IS GAINING INCREASING IMPORTANCE. Features need to be extracted as needed - quickly and without a lot of button pushing, knob twisting, or frequent trips to the user's manual.

DSOs WITH FLOPPY DISK DRIVES ARE THE RULE VS. THE EXCEPTION. Almost all new units offer them - either as options or as standard features.

SOME MANUFACTURERS ARE NOW OFFERING BUILT IN HARD DISKS that are removable and thus, transferable, (via PCMCIA interfaces) to laptops or PCs.

MOST DSO MANUFACTURERS OFFER A NUMBER OF FREE SERVICES:
o Full line catalogs and price sheets
o DSOs for evaluation on your signals with a "how to use it" demonstration
o Application Notes that relate how to take specific measurements or tests
o Seminars to teach basic DSO technology
o Seminars to teach application specific techniques
o Competitive DSO COMPARISONS
o TRAINING after delivery for most rapid return on investment
o TOLL-FREE TELEPHONE APPLICATIONS ASSISTANCE to support their platforms
o Drivers for third party SOFTWARE used for remote control and analysis.

The primary American manufacturers of DSOs are:

o Fluke Corporation 800 443-5853 in Everett, WA

o Hewlett-Packard 800 452-4844 in Palo Alto, CA

o LeCroy Corporation 800 553-2769 in Chestnut Ridge, NY

o Tektronix Corporation 800 426-2200 in Beaverton, OR

(If you are outside of the United States, contact a local sales office) &#65533;

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

DSO FORM FACTORS

DSOs are now available in 5 different form factors:

1) PC CARD - A to D on a card that uses a PC's CPU and memory - PCB Style
Interesting due to low cost. Look out for noise problems from some PC's
backplanes.

2) STAND ALONE CARD - DSO on a card for embedded systems - PCB Style
Interesting due to low cost, small size, fewer noise issues - greater
functionality.

3) HANDHELD - Portable capabilities - Portable Style Battery operated for
field measurements.

4) PORTABLE - with some amount of upgrade capabilities - Portable Style
Performance approaching mainframes and low cost due to high competition,
high volume, and large scale integrations.

5) MAINFRAME - typically with plug-ins that determine performance - Lab Style
Highest cost but highest performance and greatest versatility.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

PRIMARY DSO FUNCTIONS

The 5 Primary Functions of a DSO are to:

1) CAPTURE.....the signal
2) VIEW........the signal
3) MEASURE.....the signal
4) ANALYZE.....the signal
5) DOCUMENT....the signal

CAPTURE = consider SAMPLE RATES, MEMORY DEPTH, BANDWIDTH, TRIGGER,
NUMBER OF CHANNELS, and PROBES.
(Here you should have a predetermined knowlege of the highest frequency
signal you need to digitize, what its full scale amplitudes are, and whether
or not you need to capture single shot or repetitive waveforms. If these issues
are unclear to you, review them with your sales engineer.)

VIEW = consider ADC resolution, DISPLAY resolution, Display size,
DSP results, and ZOOM EXPANSIONS.

MEASURE = consider PULSE PARAMETER requirements, CURSORS, and STATISTICS.

ANALYZE = consider DSP, PASS/FAIL Testing, MASK Comparisons, and EYE Diagrams.

DOCUMENT = consider PRINTING, SCREEN SHOTS to DISK, and DATA TRANSFERS.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

APPLICATIONS

DUE TO EXPANDING FUNCTIONS AND CAPABILITIES, DSOs lend themselves to a
wider variety of application areas. Like a computer, the more applications you
can use an instrument for, the more valuable it is and the easier it is to
justify. Here are a few for you to consider:

o The most obvious one is to use a DSO as an OSCILLOSCOPE. Typical
applications are electronic circuit design and debug and troubleshooting

faulty or intermittent circuits.

o Another common application is as the front end of a DATA ACQUISITION SYSTEM. DSO's cost per channel has become very competitive. Many people find that the triggering flexibility, deep memory, "live" view of waveforms, and fast transfer rates make the DSO a great candidate. If your experiment is short lived, it is nice to have a DSO when you are done vs. a black box that gets shelved and forgotten. Typical applications are research experiments, process monitoring, and flaw detections.

o DSOs lend themselves to being fully integrated into ATE SYSTEMS. In this example, the DSO is under remote control from a host computer and conducts its business by computer command. Typical applications are incoming Quality Assurance of components, Manufacturing/Production Functional Test, Final Test, and System Test.

o DSOs can be used (card level or portable rack mounted form factors) and can be embedded into systems that require Analog to Digital conversion and data analysis. Here the DSO is used as a SYSTEM COMPONENT and eliminates the need and time of engineering custom devices.

o DSOs DISPLACE/REPLACE MANY DEDICATED INSTRUMENTS - i.e. DMMs, Spectrum Analyzers, Impedance Analyzers, Time Interval Analyzers, Frequency Counters, Pulse Counters, Power Meters, etc.

Some of the common DSO Application fields include:
o Aerospace
o Automotive Electronics
o Avionics
o Chemistry
o Computer Backplanes/Interfaces
o ElectricalComponents
o Electric Power
o EMP/EMI/EMC
o LASERS
o Lightning Studies
o Magnetic Media <Disks>
o MATE
o Medical
o NDT
o Networks/Communications <ATM, FDDI, Ethernet, AX.25,etc.>
o Noise/Acoustics
o Power Supply Design/Manufacturing
o Process Control
o RADAR
o Semiconductor Design/Manufacturing
o SONAR
o Telecomm (Switches, Cellular,Telemetry)
o Ultrasound Vibration/Mechanical Analysis

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

ADCs

ADCs - SPEED
LOOK OUT for short record length DSOs that can only sample at maximum rates for short periods of time. Ideally, the sample rate value should be displayed on
screen all the time. BE CERTAIN YOU CAN SAMPLE FAST ENOUGH IN REAL TIME (SINGLE SHOT) MODE ON ALL CHANNELS NEEDED FOR THE RECORDING TIME NEEDED SO AS NOT TO ALIAS!

Another point of confusion are SAMPLE RATES specified for REPETITIVE vs. SINGLE SHOT acquisitions. REAL-TIME refers to SINGLE SHOT and RIS refers to Random Interleaved Sampling. RIS is sometimes called ET or EQUIVALENT TIME sample mode.

The sample rate speed of the DSO's analog to digital converter is a very important specification. It is the minimum time between each sample. For instance, a 500 MS/sec. sample rate relates to 2 ns. per point resolution. Multiply the number of sample points * the sample period to determine a DSO's maximum recording time @ maximum sample rate.

Many people confuse the SAMPLE RATE speed with the BANDWIDTH. BANDWIDTH is simply the analog front end performance (preamplifier and sample and hold circuitry).

ADCS - RESOLUTION
This refers to full scale resolution. An 8 bit digitizer will divide full scale input voltages by 255 counts. Thus the minimum discernible sampled value on a 1 volt full scale 8 bit DSO would be 1 / 256 or .00390 volts per step.

If you have repetitive waveforms, you can increase your vertical resolution with AVERAGING.

If you have transient waveforms, you can increase your vertical resolution by low-pass filtering each sweep <FIR> for ENHANCED RESOLUTION.

ADCS - ACCURACY
Not all ADCs are created equally. The most common figure of merit is EFFECTIVE BITS that relate the number of correct bits of a given ADC's actual measurements vs.ideal.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

BANDWIDTH & TRIGGER

BANDWIDTH
BW is the amount your signal will be attenuated by the DSOs front end amplifier - specified at the -3dB point - as a function of input frequency. Remember that BW ratings are at the input to the amplifier and that your PROBES might also attenuate your signals. If you are looking at signals > 50 MHz, try a FET probe.

Remember that -3dB is down in amplitude by almost 30%. You probably DON'T want a 30% error in your amplitude measurements. Consider the higher BW DSOs so your measurements will be accurate.

LOOK OUT! Many DSOs have BW ratings that reflect their best performance but only in certain voltage ranges.

LOOK OUT! Some DSOs reduce sample rates by the number of channels activated. This could cause aliasing by changing the relationship of how fast the DSO is sampling vs. the BW of the signals you are digitizing.

Many DSOs have analog BW specifications far greater than their SINGLE-SHOT sample rate's Nyquist (.5 sample rate) frequency. This is so that when repetitive waveforms are viewed, the maximum BW signals can be seen.

TRIGGER
If you can't TRIGGER on the waveforms you need to see, you have a real problem! This should be center stage for your demo if you are looking at a new DSO. There are various trigger capabilities and a combination of them that are easy to use that capture your waveforms is the most desirable.

Know how frequently you need to trigger. The maximum trigger rate is a key specification that isn't often published in manufacturer's specifications as there can be many variables. Evaluate and compare!

Some DSOs have a MEMORY SEGMENTATION feature that lets you trigger very rapidly and fill just a portion (1 segment out of #n segments) per trigger.

Most DSOs will let you trigger on the width of pulses <GLITCH>, the INTERVALS between pulses, the LOGICAL or PATTERN conditions between inputs, after specific delays by events or time, drop out conditions, etc. Compare!

Look for TRIGGER ICONS that relate how the current trigger selection is working. This is very helpful if you are looking at a screen dump later and trying to reacquire with the same trigger conditions.

DSOs are valuable tools for looking at video signals but not all DSOs offer a video trigger as a standard feature. Compare!

DSOs can almost always capture single shot events but not always with the amount of pre or post trigger delay you might need. If your application requires capturing a lot of transient waveforms, look into the span of trigger delay as an important spec.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

ARCHIVAL & MEMORY

ARCHIVAL
FLOPPY DISKS - They are nice - should be MS-DOS and should come with file formatter so you can convert to ASCII and back then back to binary.

HARD DISKS - They are becoming available and offer the same kind of convenience that is realized in PCs.

MEMORY CARDS - They are expensive but they are fast - up to 200 times faster than a floppy. Require reader at PC to use the data.

PRINTERS/PLOTTERS - They are the best way of showing the world your waveforms and your measurements. Plotters are great for elegant color - most impressive for overheads.

ARCHIVAL DATA FILE TYPES:
WAVEFORM FILES - Binary but with conversions to ASCII for import into other programs and from ASCII back to DSO's binary format.

SET UP FILES - Most DSOs have front panel setups that you can recall and store either in nonvolatile memory in DSO or to disk.

SCREEN SHOTS - "Print to disk" graphics files that are screen dump imports into your word processor.

MEMORY
Tricky! Manufactures specify their largest numbers. Look out for some DSO's acquisition memory values that divide by the number of active channels.

Don't confuse acquisition memory with reference memory specifications. Reference memory is used for copies of waveforms recorded earlier and made available for comparison either by viewing or by mathematics. Some DSOs have longer acquisition memories than reference memory. Compare!

Not all DSOs have the same number of reference memories. More are better. Make sure they have the width to contain your processed data. You can't store 12 bit averaged waveform data in 8 bit reference memory. Compare.

Not all DSOs have the same number of memories for front panel set-up/storage and recall. Compare.

Some manufacturers offer MEMORY CARDS for additional reference memory.

Some DSOs allow for MEMORY SEGMENTATION where you can acquire multiple trigger events in a single sweep display. A few models will also record the time of each trigger event that occurred.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

DISPLAYS

NOT ALL DSOS ARE CREATED EQUALLY - ESPECIALLY THEIR DISPLAYS! The best compact an entire sweep of acquisition memory onto a single screen with a min/max algorithm. The benefit is that you don't have to page thru screens to see the interesting details in your data. Min/max compaction makes faults obvious.

IDEALLY, THE SCREEN WILL BE LARGE enough so that you can see the WAVEFORMS and MEASUREMENTS clearly at the SAME TIME. Look out for small diagonal measurement displays that put measurements on top of the waveform data.

DSO displays are typically specified in terms of resolution and diagonal size. The higher the resolution, the easier it will be to see fine details and the better your publications that have imported DSO screens will appear. The larger the diagonal size, the greater the chance of being able to see critical information on screen all at the same time vs. pages of menus.

IDEALLY, YOU SHOULD HAVE ALL THE INFORMATION ON SCREEN THAT YOU WANT IN YOUR REPORT. Consider things like trigger parameters, ICONS, measurements, input and timebase settings for each trace, sample rate, cursors and their measurements for each trace, clock/calendar. That is a lot of information on screen. How does it look?

IDEALLY, YOU SHOULD HAVE THE ABILITY TO EXPAND OR ZOOM in on DIFFERENT PARTS of your waveforms to see details more clearly and to limit your measurements to within a given region of data. This means MULTIPLE EXPANSION WINDOWS are best.

Ideally, the graticule <grid> should be done in software and allow multiple traces to be displayed, each within their own grid. This preserves the full scale voltage input ranges for best accuracy.

Ideally, the DSO display should have a report of what the front panel status is so that the entire setup of the DSO can be observed, verified, replicated, and printed.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

MEASUREMENTS

NO MORE FINGERPRINTS ON THE SCREEN FROM COUNTING GRID SQUARES! Modern DSOs display precise measurements of any waveform you capture.

Measurements are either made with CURSORS or automatically with PULSE PARAMETERS such as as RISE TIME, RMS, FREQUENCY, etc. seen right on the display.

Ideally, the PULSE PARAMETERS should include STATISTICS so you can see and measure HOW MUCH YOUR WAVEFORMS ARE CHANGING with every new trigger or acquisition.

Cursors should show:

ABSOLUTE AMPLITUDE at a given point

ABSOLUTE TIME <from trigger> at a given point

RELATIVE AMPLITUDE <difference in amplitude between any 2 points>

RELATIVE TIME <difference in time between any 2 points>

Ideally, EACH TRACE should have its own set of cursors for SIMULTANEOUS measurements on all displayed traces.

You should be able to make measurements automatically on all displayed traces.

PAY CLOSE ATTENTION TO THE DSO'S ABILITY TO DETECT AND MEASURE SIGNALS THAT ARE CHANGING. THIS IS OFTEN OVERLOOKED AND YET IT IS OFTEN THE MOST NEEDED CAPABILITY.

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

DIGITAL SIGNAL PROCESSING <DSP>

DSP is doing math on the waveforms so additional information can be obtained.

Some instruments really slow down when DSP is being performed. Ask for benchmark specifications on the key functions you need. Don't waste your time looking at DSOs that just aren't fast enough.

Another DSP concern is that some manufacturers don't process an ENTIRE waveform because of poor CPU power. Make sure the data you need processed is really being processed!

Another DSP concern is that you may wish to do a SERIES of functions. How many functions can be chained varies from model to model. Compare!

Consider these potential DSP functions:

Arithmetic (Add, Subtract, Multiply, Divide any traces)
Averaging (Remove random noise, improve resolution)
Enhanced Resolution (Smoothing, improves resolution at reduced BW)
Functions (Integrate, Differentiate, Envelope, etc.)
FFT (Spectral analysis of any trace)
Histograms (Distributions of measured values)
Pass/Fail Testing (Comparisons of live waveforms to masks or measurements)
Trending (Time series of measured values)

||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||||

DEMOS & PURCHASING

BEFORE THE DEMO
BE IN TOUCH WITH YOUR BUSINESS NEEDS as they relate to your DSO needs. Are you going to faster designs soon that might impact the banner specifications you'll need in the near future?

WRITE DOWN EXACTLY WHAT YOU EXPECT THE NEW DSO TO DO. Make it your "Wish List". Try to find out what the most popular DSO is for your application.

GET A SENSE OF HOW SOLID YOUR BUDGET IS and how soon you can place an order once you make a decision. If it is more than 6 months away and your short term needs are critical, consider rental or lease.

PLAN SEVERAL DIFFERENT DEMOS WITH DIFFERENT MANUFACTURERS. Let them know it is a "competitive situation" and you want the best DSO you can get that meets your needs. You'll get a lot of attention and the best of services.

SCHEDULE THE DEMOS IN YOUR LAB INSTEAD OF YOUR CONFERENCE ROOM. You'll be closer to your signals and the real environment <what noise?> where the DSO will have to work.

YOU SHOULD PLAN TO SEE A DEMO OF THE EXACT MODEL DSO YOU ARE THINKING OF USING - with all the options you believe you'll need - conducted by a Sales Engineer that knows the instrument and what you need it to do extremely well.

THE DSO MANUFACTURER's SALES ENGINEER SHOULD BE A GREAT RESOURCE TO YOU. By reviewing your application and assisting you with a model selection that is technically correct, your demo will be much less likely to disappoint you or anyone else.

If you have never met the Sales Engineer, plan to start with a quick tour of your facility. Explain why you need the DSO showing them the area that it will be used in and what you expect it to do. The tour may let your Sales Engineer see things that will help you that you hadn't thought about.

DURING THE DEMO
A quick overview of the DSO's banner specifications and key features is a good place to start the demo. Focus quickly on how to drive the front panel and how to extract the various functions. If it looks complex, save front panels you'll need to recall. Ask questions.

You should see your signals on screen EARLY into the demo and plan to borrow the DSO for at least a few days to evaluate it if the demo goes well.

THE DEMO SHOULD PROVE THAT THE DSO MODEL BEING DEMOED CAN DO YOUR SPECIFIC APPLICATION(S). If the demo can't do that, you are probably wasting time by evaluating it further AFTER the demo. If the DSO has to do a specific task, see it happen at the demo and learn how to replicate the settings so you can do it after the Sales Engineer leaves.

PAY ATTENTION TO THE NUMBER OF BUTTONS that have to get pushed to go from one operation to the next. If the demo is really canned, force some hopping around so you see typical vs. streamlined operation.

Find out how long the DSO model you are looking at has been on the market. Ask for MTBF figures <Mean Time Between Failures>. Find out where the closest service center is and how long a typical repair or calibration turnaround might take.

If you are a LARGE company, find out who else in your company is using the same/similar DSO from the Sales Engineer. Chat with the other users.

If you are a SMALL company, find out who else in your industry within your area is using the same/similar DSO from the Sales Engineer. Chat with the other users.

Take as much time as you like. Don't rush it. Ask questions. Record answers. Enjoy the process. If you get saturated, take a break and return.

Check the demo DSO that will be left for evaluation to make sure:
o That it will accept your full scale voltages
o That it samples fast enough to capture your waveforms with high fidelity
o That it is not affected by other signals in your environment
o That it has the options necessary to take your measurements
o That it has a manual covering operations
o That you have the applications engineering telephone number for support during your evaluation period

DURING THE EVALUATION
MAKE NOTES OF THE QUESTIONS YOU HAVE AND RECORD THE ANSWERS. It will keep you focused.

CALL THE FACTORY'S APPLICATION'S GROUP AND TEST THEM to see how well they answer your questions. Get application notes sent to you that address your areas of interest. Is there ever a telephone or service charge for contacting

them?

DON'T BELIEVE THERE IS ONE DSO THAT DOES EVERYTHING. Most labs have a variety of DSOs for various functions.

Try this experiment with the DSO you are considering. Connect a signal source up to the DSO where you can vary the amplitude of the signal by very small amounts. The waveform should have at least 3 or 4 complete cycles on screen and be 90% of full scale. Once you have a stable trigger, store a copy of the waveform into a reference memory. Then activate math so that all new waveforms are being subtracted from the waveform in reference memory. See how little you can change the amplitude level on the generator to see and measure the difference with the DSO. Remember: A large part of the utility of a DSO is verifying that things are exactly as they should be and seeing when they aren't.

AFTER THE EVALUATION
IF THE DSO DIDN'T MEET YOUR EXPECTATIONS, MAKE SURE YOU KNOW WHY and include the new things you've discovered in your Wish List that you've learned.

PURCHASING
Get a list of ALL OPTIONS available for the DSO so that you can order the exact configuration that really addresses your needs. Make sure you and your Sales Engineer determine issues that might include:
o Memory Expansion Options
o Waveform Processing Options
o Disk Drive Options
o Printer Options
o Hardware Options <External clock, video trigger, I/O, iso amps,etc.>
o Active Probes
o Probes with different attenuations than those supplied with the DSO
o Scope Cart
o Rack Mount
o Hard Shell Transit Case for safe shipping your DSO to remote sites
o Probes for all channels <Not all DSOs come with a probe/channel!>

You should also explore the manufacturer's policies and costs regarding:
o Applications Assistance
o Calibrations- NIST, MIL, Performance Checks, ISO-9000, At-Site Service
o Capabilities for Training Users
o DSO System Software/Firmware Upgrades
o Warranty Period - Extensions

You should GET A WRITTEN QUOTATION that relates the model, specifications, options, all costs, delivery, and any discounts available. Most manufacturers offer Educational, GSA, Quantity, and/or Demo discounts if you qualify.

You might also consider rental or leasing options. Most rental companies offer equity rentals where rental/lease fees apply towards purchase. AT&T CAPITAL CORPORATION is an excellent source of information concerning this

There are some very pricey professional HF receivers by Watkins-Johnson,
Racal, etc that STILL have variable BFO in the CW mode.

Very pricey receivers.......

3448. re: Why variable BFO?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-07 00:00:00 UTC
From: ian.mitchell@research.utas.edu.au
Message-ID: <403u77$i4j@franklin.cc.utas.edu.au>
Source record: 111456

In article <1a6_9508061528@mba.mba.org>, Michael.Black@juxta.mba.org says...
->
->ian.mitchell@research.utas.edu.au (Ian Mitchell) is wondering
->why the low cost shortwave receivers have tuneable BFO's while
->the more expensive ones have a LSB/USB switch.
->
->I would think cost has a lot to do with it. If you assume that
->the switch selected BFO's are crystal controlled, then the cost
->of the crystals is not warranted for inexpensive sets. IN the
->early days, I'm sure all BFO's were tuneable, and then only later
->did crystal control arrive. Thinking about it now, crystal controlled
->BFO's probably didn't show up in amateur receivers till receivers
->intended for SSB hit the market, and they were of course the
->expensive receivers. The low end receivers have basically stayed
->the same.
->
->One reason for going to crystal control of a BFO was the ease of
->switching between the two sidebands. When the receivers started
->getting sharp filters intended for SSB, you wanted the BFO right on
->the slope to take advantage of the sharpness of the filter. If
->the BFO's had stayed tuneable, you'd always have to keep fiddling
->a bit each time you changed sidebands, to get that exact spot.
->
->And yes, your thought about the selectivity of the receiver probably
->does play a part. The cheaper receivers would tend to have filters
->with not so sharp curves, and there is not the need to get the BFO
->right at a certain point.
->
->When you start using a receiver with the relatively wide bandwidth
->intended for AM broadcast, you you could put the BFO right in the
->middle of the passband and you wouldn't even have single signal
->selectivity. It would be like a direct conversion receiver in that
->you'd get the audio image, but with better dynamic range due to
->there being selectivity, albeit wide, between the antenna and the
->product detector. A tuneable BFO in this case would have the effect
->of a fine tuning control, just as tuning the "BFO" in a direct
->conversion receiver tunes it across the band.
->
->I have thought of the possibility of building a "hybrid" receiver,
->where the first mixer would be fed with a synthesizer with something
->like 5KHz steps (it's easier to build a quiet synthesizer as the
>-tuning steps get bigger), then put it through an FM-type crystal
->filter at 10.7MHz, and either put a direct conversion receiver
->after that or a second mixer with a 5KHz tuning range to take it

->down to lower frequency final IF where there is a narrow filter
->and product detector. It would be a way of getting a relatively
->simple general coverage receiver, but with the advantages of
->synthesizer tuning.
->
->I remember seeing one receiver in QST from about 1958 or so (the
->year before I was born, so I read it a number of years later) which
->was a single conversion six meter receiver. It used in the IF a
->then relatively new item, a manufactured crystal filter in the HF
->range, and having something like a 4KHz bandwidth. It used a
->crystal controlled BFO, which makes sense since it's easier
->keeping a crystal on frequency than an LC-tuned oscillator. But
->the BFO was right in the middle of the IF. The idea being that
->the filter was wide enough for things like CW and even SSB that
->you could tune the receiver until you got the right beat note
->and everything would be fine.
->
->I hope that helps, and I'm glad you found the 10.245MHz crystals.
->I'm not sure how the Australian dollar converts to Canadian these
->days, but the price you mention sounds not too expensive, which is
->the right price.
->
-> Michael VE2BVW

Thanks for that Michael, much appreciated.

As you've problably guessed I'm trying to design a general coverage receiver using the MC3362 FM receiver chip. This device has two mixers and osc's with IF's at 10.7MHz and 455KHz. The first LO is variable while the second is fixed at 10.245MHz - hence my enquiry on the crystals.

I've tracked down the filters (ceramic) which are quite low cost, luckily.

For resolving AM, I'd like to use the ZN414 (MK414), because it has good gain, built in AM detector and AGC. The signal for it being taken from the output of the 455KHz filter via a switchable SSB section - explained below.

Instead of using the built-in VFO, I've designed a simple DDS, controlled by an MC68HC705K1 low cost microcontroller from Motorola. The DDS is implemented using an EPM7096 PLD from Altera. I'm hoping to avoid having to use an AD converter by connecting the high order bit of the accumulator directly to the 3362. The mixers in the 3362 look a lot like the Gilbert type, so I'm hoping this idea works! I've calculated the fourier spectrum using a spreadsheet, and it doesn't look any worse that a square wave!

Anyway, the other function of the PLD is to generate a 455KHz BFO signal, under the control of the microcontroller. The BFO signal is also a TTL square wave.

So, the problem is to mix the BFO signal with the 455KHz IF so that the ZN414 can detect it for SSB. My idea so far is as follows:

Since the 3362 provides the correct loading for the 455KHz, a JFET, with its high input impedence could be used to tap off the signal from the output of the IF. Following this a common emitter amp with its emitter resister connected to the BFO output instead of GND, and the output feeding the input of another 455KHz ceramic filter, followed by the ZN414.

For AM the output of the BFO should be held low. For SSB this arrangement would thus cause the signal to switch on and off at 455KHz, but the 455KHz filter would reduce the harmonic content leaving a signal for the detector.

So, I am wondering if this method will work ok, or is there a simpler way?

I am open to, and appreciate any comments.

Cheers and thanks, Ian

3449. Re: Good SPICE book

sounds like Autocad to the rescue here...of course it'd be better if you could kick out a net list to feed other analysis tools...but you said dos/windows, not unix.

one hint. do all the work with a standard parts library and then do any resizing at plot time. the computer and your postscript laser printer are better at this than trying to draw every part to a different scale just so the completed circuit fits the screen or paper. most programs will have some form of scale function in the output routines that affects the output only and frees you from having to ever worry about that.

Do rotary encoders "go off" after a year or so? Can they be repaired? Do they lose their magnetism or is it just dust which gets inside?

I have a couple of digital radios which can be tuned by a knob, one cheap, one expensive. In both cases, after a year's use, the frequency started to dither around slightly whilst I smoothly turned the knob. I had thought this was due to a brain-damaged chip but now think it must be the rotary encoder.

Many thanks,
Andrew Thomason (andrew@dpmms.cam.ac.uk)

Yes, go to any aviation repair shop or supply store (your local small puddlejumper airport mechanic can help you find one, or there are a hundred of them listed in a magazine called "Trade-A-Plane). We use stainless steel wire in many gauges for tying bolts and nuts down; it is called "safety wire". You can probably talk the mech into giving you a few feet; a full roll is only a few bucks or so.

Titanium, on the other hand...

According to my Cirkit catalogue, the Alps low-cost mechanical encoder
has a service life of 10^6 cycles. They cost #8.95 in the UK if that is
what is used in your radios.

They should not. You may have really cheap encoders - mechanical contacts
rather than optical or magnetic design. These can be cleaned if you can
get at them.

The other types should last a long time.

Sounds like Orcad to the rescue here. :-)

It's much easier to use than Autocad for schematics, outputs a netlist
compatable with a number of autorouters, etc. The only drawback is that
it isn't cheap, but then neither is Autocad. A cheaper program is Supercad.
It has most of the drawing features of Orcad, but for only $99. It isn't
as good for complex designs, though, because it won't work with a hierarchy
of sheets, won't auto-number parts, make bills of materials, etc, but it
is adequate for most amateur projects.

An ideal setup is Orcad as a frontend for Pcad. *Now* you're talking
bucks, but it automates almost all of the tedium of translating an
idea to a schematic and circuit board layout.

Actually, I think it anneals the copper wire wound on the toroid and makes the windings less likely to move and change the inductance of the assembly. Doesn't actually affect the toroid, although they can be affected by high temps but I think it takes much higher than 100C.

From: aturbide@barint.on.ca
Message-ID: <405gmj$g3p@galaxy.barint.on.ca>
Source record: 111471

I bought a Zetel SDP 600 autopatch a while ago and it worked great
until for some reason or other the Intel microcontroler chip bit the
dust. I tried contacting the place I bought it from the they couldn't
help me out there. (they're only a distributor). I would need the
phone number or address that I can reach Zetel or other dealer that
could supply me with this chip.

From: tvr@boulez.CNMAT.Berkeley.EDU
Message-ID: <TVR.95Aug7192456@boulez.CNMAT.Berkeley.EDU>
Source record: 111374

I'm NOT an expert on the 'lowfer' band, i'm just learning about it myself.
Hopefully, an active 'lowfer' can answer these questions more authoratively.
However, i can clear a few things up.

From the article "Ground Zero" (Popular Electronics-Oct.'94):

1750-Meter Experimenters' Band:
- 160-190 kHz - Max. power-1watt
- Max. antenna length-50 ft. including ground lead and transmission line
- Modulation-any
- Out of band emissions must be supressed by 20 dB.

I have that one quoted in my WWW page simply because it contains a magazine
reference. 50 ft is approximately 15 meters, as later posters have noted.

I don't care what THAT book said. It was either a misprint or a typo on
your part....
because I respectfully must imform all that the limit of the combined
feedline and antenna
system for transmitting can only be a maximum of 15 (fifteen) feet.

No, it is 15 meters.

(b) The total length of the transmission line, antenna, and
ground lead (if used) shall not exceed 15 meters.
[Sec. 15.217: Operation in the band 160-190 kHz.]

Reference:
http://www.pls.com:8001/cgi-bin/taos_doc.pl?unix+1+cfr+187927+query+%27Sec.+15.217%27%3acite+%25BREAK%25+cfr%3a
(or type "'Sec. 15.217':cite" at http://www.pls.com:8001/his/cfr.html)

Someone asked about IDs:

It is also interesting that you literally can make up your own callsign/id
on there (trying not to duplicate an existing one) If you are allready a
ham you can use your call as it is very unlikely
that it is allready being used on vlf! Most IDs are 3 letters in lenght in
the entire vlf band.

I don't have the reference nearby, but i understand that the 'lowfer' folk
use their callsign suffix. (I'm not sure what Advanced, Extra and folks
with "by 1" calls use.)

I wouldn't use an amateur call as the transmissions are clearly
out of any amateur band.

Exactly, and that's the reason for the callsign suffix convention. So, if i were to operate there, i would use PAG to identify and explain to anyone who asked that my amateur callsign is KD6PAG for purposes of providing a convenient mailing address and operating under Part 15.

If you live near salt water, use it as a ground and place the x-mitter directly at
the base of the antenna. The vertical portion would then be 15 feet (constructed with a copper ribbon/tubing or multi-wire to compensate for R-loss) with a large capacity hat to bring the resonance down as far as possible without having the outer perimeter of the capacity hat fall below 20% of the vertical portion of the antennas' vertical mast

I'm not sure what the 15 meters means. For example, i don't know whether it could be something like a 14 foot ferrite-rod with a 1 foot ground rod, both connected directly to the transmitter. That may be a "gray area" in the regulations. On the other hand, if you keep things real clean and don't annoy anyone, the question won't come up. (Of course, if you have a horrendously large receiving antenna, which is perfectly legal, non-hams won't know the difference, and questions might get asked.)

If you're seriously interested, here's a useful reference:

The monthly newsletter is called "The Lowdown" and is published
by Bill Oliver, 45 Wildflower Road, Levittown, PA 19057. The cost is
$15 a year. It cover all lowfer, medfer, and other interest in the VLF
area. I find it to be quite interesting. Also, there is a couple of
different systems available for computer operated beacons. A lot of
activity in all areas of the country. Some are hams and other seem to
be engineering types. I am in the process of building a station now.
[daleh@skypoint.com (Dale A. Hagert), 23 Apr 1995]

Have a good time, but behave yourself.

-- KD6PAG (who is still learning)

P.S. I'm still looking for a local (S.F. Bay Area) 'lowfer' to help me get started someday.

3466. Re: Modulating VCO's

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-08 00:00:00 UTC
From: tvr@boulez.CNMAT.Berkeley.EDU

I'm looking for some pointers to detailed work on modulating vco's and synthesizers for transmitters. I'm specificaly looking for more information on Dual port modulation for FSK data. Technical reports are fine, application notes, etc.

A recent project or two on DDS (direct digital synthesis) in either "QST" or "73" magazine uses the HSP45102, simplist of the Harris DDS chips, along with a video DAC as a VCO intended for HF use. That article doesn't use the feature, but the chip can store two frequencies. You put your digital input into the frequency select input of the DDS chip and load the right data into the chip and you get instant FSK. That datasheet is available via their AnswerFAX service:

http://www.semi.harris.com/datasheets/dsp/hsp45102/

You'll have to use a mixer or multipliers to get it up into a band where it'll make much difference. (Be careful about spectral purity if you start from a "73" article, as i don't recall seeing very much documentation in their articles about that and it makes me wonder about that. If you're operating under an amateur radio license, you can't hide behind Sec. 15.23; e.g. it doesn't matter if you "may not possess the means to perform the measurements for determining compliance with the regulations", you still must comply.)

I suppose that you might be able to do something like that with one of the Motorola synthesizer chips that uses parallel inputs, choose parameters very carefully and can come up suitable configuration in the feedback loop. However, i don't think that's necessary. Their ordinary transmitter ICs should work just fine for what you want, you just have to figure out where to inject the signal. See the MC13175/176 UHF transmitter IC data sheet for details (includes both AM and FM modulation). These datasheets can be obtained from the Motorola fax-back service, which is available via:

http://motserv.indirect.com/home2/fax_rqst.html

as i don't think they have either of those devices on-line yet.

Yep, boiling water indeed! Complete with winding. Supposedly this also helps relieve winding stresses by expanding/contracting. It helped some.

Thanks for the replies, folks. The consensus very much goes with AIR-CORE COILS for the best VFO stability. Ceramic forms are best, with glass tubing and acrylic rod also possibilities. Toroids are a compromise for compactness at best, which may work OK at lower frequencies, but they don't have the temp. stability of air core coils.

Hi. I was wondering if anyone had schematics for a small FM transmitter.
I need to design a wireless FM microphone for a school project. It needs to
be capable to transmitting to at least 20 feet away, to an ordinary FM
receiver. E-mails would be appreciated, but I will check the newsgroups.

Thanks!

I use Orcad with Eagle 3.0. This combo is excellent and very easy to
use. It handles just about any type of board from simple to complex
surface mount. Eagle (CadSoft) also has a schematic module, but
I haven't used it.

Got the optoisolator handled, I think: I've gotten several e-mail
messages indicating the manufacturer, and if I can't cross-reference
it with that info, I remember seeing one in the Mouser catalog that
looked like a functional equivalent.

>> The other part of the project that's missing is the PAL used to

Aaron> Yes, you will need to program the PAL, and it is not a trivial
Aaron> process. Tools exist for developing PAL programs, but they
Aaron> cost $$ - Can you get away with just using logic gates???

I _think_ I _probably_ could do that, but I'm really at the outer
limits of my current understanding, now. The text that came with the
schematics is minimal, and so I'm not absolutely sure how things are
being decoded. Is there anyone who might be able to help me figure
out what I could do to substitute gates for the PAL? Like I said,
I've got the schematic; all that's missing is artwork (which I can
probably do without) and the logic of the address decoder. I even
have the source code (of course) for the driver programs for this
card, for Linux, if that would be any help at all.

>> [...]

>> Is there any help available for me out there?

So far there's been quite a bit of help for me, and with a little
more, I'll be on the home stretch for this project.

I also want to publicly thank everyone who's written or posted
already. Everyone's been really helpful.

There are two related gyrators that have 5 passives in series, plus
2 op amps tapped into the string at intermediate points. They are
usually called the Bruton and Antoniou gyrators and are based on
work by Riordan. (See references at end). The best treatment of these
that I have seen is in Sedra and Brackett's book on active circuits.
I would warn you that you need a GBW product in the op amps on the
order of 100 times the product of Q and frequency, so that at 160
meters, you should be looking at 200 MHz op amps like the OPA620 or
even more. Also, I have not seen any "basic" treatments of this
complicated topic in my extensive literature searches for gyrators.
Perhaps you should go back to passive inductors.

From: mfschick@aol.com
Message-ID: <408jet$iac@newsbf02.news.aol.com>
Source record: 111386

I have an old Swan Mark I amp that I would like to modify and improve for 3-28MHz. This amp has two 3-500Z tubes in push-pull, cathode driven AB2 configuration. One of the modifications I would like to do is to install a tuned Pi-L input filter to help cut out harmonics, etc. I am trying to find the characteristics for the 3-500Z tubes so I can calculate the component values in the tuned filter, but haven't had any luck. Does anyone know what the input impedance, plate impedance and other parameters of this tube are in a ground grid arrangement (plate voltage of 2.5KV) and how to calculate the actual impedance see by the filter when two of these tubes are in connected in parallel in the amp? Any help on the subject would be appreciated and thanks in advance.

3478. Re: looking for plans: CB base antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-08 00:00:00 UTC
From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <408rsu$mop@newshost.lanl.gov>
Source record: 111387

I built several of these for 10 meters, but they will work
equally well on 11 meters (if your kid enjoys the CB he is
twisted beyond belief, get him a Novice or Tech ham radio
license guidebook from Radio Shack):

```
| ^
| |
| |
| |
| length: 103" CB or 99" for 10 meter ham
| |
| |
(aluminum tubing | |
or 1/2" galv. | |
elect. conduit) | |
| -
T < insulator: block of wood or plastic
I -clamp vert. element to insulator with
I steel hose clamp(s)
---------------------------
< 4 radials ea. 103" long >
(side view of antenna)

|
|
|
|
| Attach coax shield to radials
^/
-------/o\-------
\ /\
T Attach coax center conductor to vert
| element, may clamp under hose clamp
|
|
|
```

MAke the center plate of aluminum or whatever you have
handy, 6 to 12 inches square will suffice. Attach the
4 radials to the center plate with screws and nuts for
a good mechanical and electrical connection. The
Center vertical element MUST be insulated from the
radials (horizontal elements).
This antenna will support itself just sitting on a flat
roof or other surface, even out in the back/front yard on

the ground.
The higher you can get it of course the better it will
perform - as with ANY antenna.

Howdy,
You later point out that you're assuming simplex operating. In a simple
design, the PLL does not need to be re-programmed from rx to tx, since it can
operate at the same frequency (if the IFs for rx and tx are the same). A
single PLL simplex transceiver can be made to switch from rx to tx very
rapidly, but this isn't a common technique because the market for simplex-only
radios is very small.

3483. MDS downconverters good for parts?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-09 00:00:00 UTC
From: jkesling@shell.portal.com
Message-ID: <40b9vi$8s8@news1.shell>
Source record: 111324

I recently obtained several MDS downconverters. I believe they had
been used by a now defunct local business to provide direct to your
home premium TV broadcasts.

They have an "N" connector input and two "F" connectors for output, one
is labled "test" the other "TV". They are labled "INPUT MDS CHANNEL 1"
and "OUTPUT CHANNEL 3". They are obviously designed to be mast mounted.
They appear to have a preamp built in as well as a crystal controlled
oscillator and mixer stages.

Does anyone know the frequency of MDS CHANNEL 1?

Should they be scrapped for parts, converted to another frequency,
used as-is or thrown away? Other suggestions?

John

I am looking for data on the old Amperex twin tetrodes intended for VHF service in the land mobile and avionic industry,circa 1970.I have a copy of an Amperex flier circa 1966 but there were several released after that.

3485. US Military Field Expedient Antennas

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-09 00:00:00 UTC
From: pglibber@uk.oracle.com
Message-ID: <9508090927.AA22216@ukpyr2.uk.oracle.com>
Source record: 111390
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I have some fairly basic questions that I would appreciate your help and guidance with.

I have been reading a US Army Special Forces manual which discusses various types of improvised, field-expedient antennas such as:

Ground Plane
Horizontal
Long-wire
Half-Rhombic
Doublet

I'm writing from the UK and the references mentioned in the manual are not at all easy to come by - I've tried.

1) In the case of some of these designs there is a need for a 'ground'. The diagrams in the manual show one end of a wire attached to a metal stake which is pushed into the ground, while the other end is attached to the radio set itself. Where on the radio set is the free end of the ground wire attached ? Is it attached to some kind of socket, or do you somehow attach it to the body of the radio set ?

2) When using a 1/2-Rhombic the manual mentions that you feed the two 1/4 wave antenna elements from the centre using a 'coax'. What exactly is a 'coax' and how does it differ from the antenna wire itself ?

3) With the 1/2-Rhombic design the manual suggests that if a coax is not available to use a 'twisted pair'. What is a twisted pair ? My guess is two sheathed copper wires twisted together - but is this too simple a thought ?

4) With the 1/2-Rhombic one end of the antenna wire is attached to a terminating resistor. The idea of this resistor is to give some directionality to the radio wave (I recognise that there is a difference between a resistor and an insulator (in the later case, the manual suggests a piece of wood or a C-ration spoon)). Does anyone have a good idea of what would make a good field expedient resistor ?

Thanks,

Peter

Hi Dan, You have an old channel master rotor, and all of the 3 wire rotors were basically the same. A new control box will run you old motor. I believe its something like 20 volts AC to run the thing if you want to make your own control.
We just used one of those beasts this last field day....but we had a 12V DC motor installed in it (we were QRP Battery) it worked quite well.

This is however, not what David is after, as he specifically mentioned
vco's and synthesizers. If you are using the variable crystal approach, it
is much better to use a varactor diode in conjunction with the crystal so
continuous frequency changes can be effected. Simply switching leads to a
lot of undesired sidebands.

The conventional "single oscillator" (my term for it) VHF FM transciever is
turning out to be quite inadequate for high-speed FSK packet, at least in
the versions supplied by the Japanese manufacturers. The primary
limitation of this design is that the PLL must re-lock on every change from
transmit to receive and vice versa. Thus the radio is unable to transmit
or receive for a period of 100 or more milliseconds at the beginning and
end of each transmission. Since 9600 baud packets can be less than 25 ms
long, this is a tremendous waste of channel capacity.

Another major problem with the single oscillator set is that in order to
tune fast from TX/RX, the loop filter must have a wide bandwidth, on the
order of 100 Hz or more. But with a wide feedback bandwidth, the PLL will
"fight" the modulation, causing a great deal of distortion of the
transmitted signal unless rather elaborate compensation is used. The
compensation is likely to require individual adjustment for each unit. It
may be possible to lower the bandwidth to a few Hz once lock has been
achieved, but this is likely to push out the RX->TX transition time even
more.

A much better design is a heterodyne system. Here the PLL runs continuously at the LO frequency. Thus the radio is always ready to receive. When transmitting is required, a crystal oscillator at the IF frequency is switched on and mixed with the LO. The output of the mixer has 3 main components, LO-IF, LO, and LO+IF. This latter signal is on the correct frequency for transmission (assuming simplex operation. For offset channels, either the VCO/LO can be retuned (slow) or another crystal for each frequency split provided (expensive)). A fairly good filter is required to reject the spurious outputs from the mixer, before the power amplifier.

Modulation is applied to the heterodyne oscillator using VXO techniques. The PLL will not distort the modulation, and it also remains locked during the transition from receive to transmit and back. Thus very fast changeover time can be achieved. This type of design used to be somewhat popular in commercial equipment. The Santec ST-144uP 2-meter HT is one example. However, the cost of the extra crystal, mixer, and filter, as well as the inherent lack of wide transmit frequency coverage (without readjusting the filter anyway) has caused it to become extinct in today's market.

3488. Titanium wire etc

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-09 00:00:00 UTC
From: dcadd@luc.ac.BE
Message-ID: <9508090909.AA18344@alpha.luc.ac.be>
Source record: 111393

Greetings from a warm and sunny Diepenbeek in N.E. Belgium!

Stephen Parry asked about supplies of titanium wire. One possibility is Aldrich Chemical Company, 1001 W. St. Paul Avenue, Milwaukee, Wisconsin 53233 tel 414 273 3850 fax 414 273 4979.

They also have stuff like tungsten, zirconium, molybdenum, nickel etc etc wire, foil and what-have-you. Prices will be high-ish as they are suppliers of research grade chemicals, rather than work-a-day ironmongery, examples:

THESE PRICES ARE IN BELGIAN FRANKS!! sorry, but that's life! (and what did you expect from Belgium!?)

titanium wire:

cat no. 34,886-4 99.99% pure 0.5mm diam 450milligrams (50cm long) BF 1824
2.7 grams (300cm) BF 6400

26,790-2 99.7% pure 0.81mm diam 23grams (10 metres long) BF 1623
115grams (50 metres) BF 5544

Stuff like titanium, zirconium, tantalum and a whole pile of other metals can be used as 'getters' (which someone asked about a few days back) in tubes.

Sorry folks, but I don't know if they will sell in small quantities to 'the public' but you can always ask, and I'm sure they will offer advice as to where you can try once you explain your intentions - I hope this helps.

If you are looking for general advice on vacuum systems etc, I'd suggest "Building Scientific Apparatus - A Practical Guide to Design and Construction" by John H. Moore, Christopher C. Davis and Michael A. Coplan, published by Addison Wesley, the old edition which I have is 1983, ISBN 0-201-05532-5, but there's a newer one, also in soft cover (the hardback was EXPENSIVE! 62 UK pounds in '88 or so) - maybe the local library could get it for you. It lists many US suppliers, but again, it's research oriented so many will be pricey and may not be interested in 'small' sales. But you can always try . . .

Hi there,

yes, same thing happened with my Kenwood R-5000 which used an optical rotary
encoder. After talking with a local Kenwood dealer here in Munich, that
was disinterested in taking the radio for service, I decided to have a go
at it myself and tracked the problem down to a bad photodetector in the
encoder itself. I was able to replace the detector with a detector removed
from an emitter/detector module of the write protect section of a junked
TEAC floppydrive. I was lucky it also fit mechancally in the R-5000 encoder.
My R-5000's tuning knob has worked perfectly ever since.

Source record: 111395

Hi Martin,

>I have an old Swan Mark I amp that I would like to modify and improve
>for 3-28MHz.

>One of the modifications I would like to do is to install a tuned Pi-L
input
>filter to help cut out harmonics, etc.

A Pi-L input filter (or even output) will not offer much, if any,
improvement
in harmonic suppression. The layout (component placement, connection
points, and lead dress) and shielding are much more important, especially
with high order harmonics. Tuned input circuits can be strange animals as
to
their effects on harmonic levels, efficiency, and IMD performance. I have
measured IMD and efficiency deterioration when a tuned input was added,
as well as cases that showed improvement!

To be safe I recommend a low pass pi-network with a Q of 2 to 5 placed
very close to the cathodes of the tubes (minimal lead length) or using
high
capacitance (very low impedance line) if the input circuit has to be
located
some distance from the tubes. Placing a tuned input a fair distance (even
15
inches or so) from the tube can kill high end (20 meter and higher)
efficiency
unless a very low Z line is used.

>I am trying to find the characteristics for the 3-500Z tubes so I can
>calculate the component values in the tuned filter, but haven't had any
luck.
>Does anyone know what the input impedance, plate impedance and other
>parameters of this tube are in a ground grid arrangement (plate voltage
of
>2.5KV) and how to calculate the actual impedance see by the filter when
>two of these tubes are in connected in parallel in the amp?

The input Z will be around 50 ohms or slightly higher for two tubes in a
good layout. There will be some parallel capacitive reactance that becomes

important above 10 MHz, and usually some shunt L (from the filament
choke) on the low end. The best way to set up the input in this amplifier
type
is to place four 220 ohm non-inductive resistors from each filament pin to

chassis. The tubes are left in the sockets and the input is aligned with the
power off and tubes cold with some type of low power RF impedance
measuring device like an SWR Analyzer or meter.

The plate impedance is a direct function of the plate current and voltage, and
conduction angle of the tube. The output source impedance is the RF anode
voltage at the fundamental frequency over the available anode circuit RF
current, so it changes with voltage to current ratio and is independent of

feedback or the actual type of tube. This is the impedance that must be
conjugately matched to the load for maximum efficiency. ;-)

At full CCS power of 1200 watts output (2500 v anode, 800 mA, 200
degree conduction angle) I calculate 1600 ohms approximately. At lower
output power levels with 2500 volts fixed supply the impedance will rise, at
higher power levels it will decrease. The output network is typically
designed for the desired Q at maximum power, and the Q is allowed to
increase if the power level is decreased. This insures sufficient harmonic

suppression and proper network operation at maximum power...where it is
most important. A range of 10 to 20 would probably be acceptable, the
lower Q resulting in less tank heating but slightly less harmonic
suppression,
and the higher Q resulting in slightly more tank heating but a little bit
better
harmonic suppression on low order harmonics. Most air variable amplifiers
with large tubes operating at high voltages must have the Q compromised to

hit both ends of the HF spectrum.

But usually there is very little change in efficiency or high order
harmonic
suppression if the Q is changed over a two to one (or larger) ratio as
long as
the components and tank layout are reasonably good, so don't be overly
concerned with extreme accuracy. Just try to meet or exceed the minimum Q
desired at full power (the Q will nearly double if you operate at half
power
with the same anode voltage anyway).

Varian will send you details on calculating the effective plate impedance
in a
book called "The Care and Feeding of Power Grid Tubes" and a 3-500 data
sheet. Call them, they have application engineers that love to be
bothered!

>Jack WB3U

The problem with posting binary/UUEncoded files here is not the
fact that occasional posting "isn't worth worrying about." The problem
is that this group as well as several others in the rec.radio.amateur.*
section of USENET are picked up by a USENET to EMail reflector
at the University of California at San Diego. The articles are gathered
and placed into digests and sent to thousands of people via EMail.
If this was not the case and it simply showed up on a USENET reader
as a topic that could be ignored there would not be much of a problem.
If someone posts a UUEncoded file here that is 50K and it is duplicated,
say 2000 times, that is 100MB of space that is taken up by ONE post.
That is why I don't recommend posting UUEncoded files here. If you have
one post it to one of the binary newgroups and notify us of its existence
by posting an article telling us where it is.

Thanks

Wayne,

I have a 4-1000 HF amp. Variable roller inductor, vac variable capacitors,
for continuous tuning. Very heavy duty power supply with 240V variac for
continuous variability.
5' relay rack (w. castors) with lots of meters,
and window to watch the 4-1000 etc.
This looks like unit built for show in handbook article.
I have so many spare 4-1000s, I couldn't resist putting a second
one in parrallel, to make input impedance 50 ohms directly.

Would you like to buy it, or just trade schematics, experience
building these? Too bad I am in California.

Speaking of expensive equipment, the $58,000 HP 8663A is a case in
point. The rotary encoder in that instrument has a relatively high
failure rate. I don't know if the failed ones can be rehabilitated
by cleaning out the dust.

I'm assuming :) you are talking about light coupled encoders. I would have to say that I disagree with the statement that they are not reliable. Some of the most expensive equipment in the world uses them and they work without fail as long as they are kept clean and properly aligned. If designed properly, they won't need alignment, but dust gets on the encoder wheel and the source/target leds and causes problems. Carefully cleaning an encoder wheel will keep it working for many many years. Case in point, check out the FT-2400. It is notorious for encoder wheel problems. The one they replace it with, I've been told, is better sealed so that dust can't get to it as easily.

Actually, optical shaft encoders are noted for their extreme reliability
and long life. About the only things that can harm them is contamination
of the optical surfaces, an electrical surge that blows the LEDs or
phototransistors, or shaft bearing failure. Now unfortunately, some of
the shaft encoders used in amateur equipment are mechanical rather than
optical, and tarnished contacts, and ordinary contact wear, take a rapid
toll.

If someone posts a UUEncoded file here that is 50K and it is duplicated, say 2000 times, that is 100MB of space that is taken up by ONE post. That is why I don't recommend posting UUEncoded files here. If you have one post it to one of the binary newgroups and notify us of its existence by posting an article telling us where it is.

Or, you can put on a WWW or FTP server, and include a URL or pathname in your posting. If you ask nicely, there are many folks out here with WWW pages who would be happy to include your schematics and drawings, along with the original text. One of the High Speed Packet pages already has a number of schematics on it, and it is very useful.

We could also request that 'alt.binary.radio.amateur' be created, i don't see much trouble getting that through 'alt.config'. Now, of course, not everyone can get 'alt.binary' as much of the material posted there is considered (depending on the site) to either consume very excessive amounts of disk or to be too controversial to be anything more than an "upon request" basis...

You are sorta right! If you use a cable ready tuner such as one in your VCR or cable ready TV you can recieve ATV on 434 on ch 56...(I think..or 59).

You have to connect an outside antenna to the cable input of your VCR. The antenna should be a direction type.

One problem. The tuner in your VCR is not as sensitive as the downconverters for ATV. The signal in your area should be a strong one such as from a repeater or a close friend. Give it a try anyhow, that is what amature radio is all about!

Rather than reinvent the wheel, why not just look in back copies of
the ARRL Handbook? That would be a lot simpler than designing the
entire tank circuit from scratch. At the very least, you would
also see how others have built these, and maybe get some ideas
regarding other component values, like coupling caps and plate chokes.

I don't understand this. If someone posts a 50K UUE binary to this group, it takes up 50K on the news server I subscribe to. If it also takes up 50K on other servers as well, how does that impact me?

Just asking.

A single oscillator PLL synthesizer can lock up in considerably less
than 100mS. I have several Motorola MCX100 transceivers that are
specified to lock up in less than 3mS. The key is to use an adaptive
loop filter; some designs shunt diode(s) across resistors in the loop
filter to do this, but it is better to use switches like 4066 quad
to modify the loop filter in a predictable manner.

>Another major problem with the single oscillator set is that in order to
>tune fast from TX/RX, the loop filter must have a wide bandwidth, on the

>achieved, but this is likely to push out the RX->TX transition time even
>more.

You are correct to point out the lock-up time vs. VCO modulation
trade-off. However, keep in mind that loop bandwidth choice is
also influenced by reference noise considerations, though this is
often not a big issue.

Don't overlook the use of "two point" modulation; modulation is applied
to the VCO and also to the reference. For example, the Motorola MCX100
I mentioned above also offers this capability. You may be able to
retrofit the ability to modulate the reference to an existing synth,
but be very careful not to make your reference source become noisy
and drifty.

Whenever you make any changes to a PLL synth, you should always do the
math first to make sure you don't break the PLL synth in some unexpected
way (like it won't lock up at all ;-).

>A much better design is a heterodyne system. Here the PLL runs
>continuously at the LO frequency. Thus the radio is always ready to

>Modulation is applied to the heterodyne oscillator using VXO techniques.
>The PLL will not distort the modulation, and it also remains locked during
>the transition from receive to transmit and back. Thus very fast
>changeover time can be achieved. This type of design used to be somewhat
>popular in commercial equipment. The Santec ST-144uP 2-meter HT is one
>example. However, the cost of the extra crystal, mixer, and filter, as
>well as the inherent lack of wide transmit frequency coverage (without
>readjusting the filter anyway) has caused it to become extinct in today's
>market.

The extra complication of the VXO, mixer, and adequate mixer image
rejection are the major issues with this. The transmit filter often
ends up being a set of helical resonators with the inherent narrow
bandwidth you mention. A decent two point modulation design can give
you the necessary DC modulation response and TX/RX switchover time
with consideranbly less complication and also remove the possibility
of inadequate transmit image suppression.

jkesling@shell.portal.com (John Darrell Kesling) wrote:

>I recently obtained several MDS downconverters.
<snip>
>Does anyone know the frequency of MDS CHANNEL 1?
>
>Should they be scrapped for parts, converted to another frequency,
>used as-is or thrown away? Other suggestions?

MDS1: 2150 to 2156 MHz
Visual Carrier: 2154.75
Color Subcarrier: 2151.17
Aural Carrier: 2150.25

MDS2: 2156 to 2162 MHz
Visual Carrier: 2160.75
Color Subcarrier: 2157.17
Aural Carrier: 2156.25

Note that the relationship of the carriers in both MDS channels is
inverted relative to normal TV broadcasts.

BTW, I haven't seen MDS-only downconverters in quite some time. Most
of these were used in the mid 70's to early 80's, following which ITFS
and MMDS (2.5 - 2.7 GHz) began gaining popularity for commercial
multichannel "Wireless Cable" use.

Note that the video standard at the higher MMDS band is identical to
"normal" television broadcasts. Later model downconverters, some of
which have dual front ends for receiving both MDS and MMDS, use a L.O.
located between the two services. Thus, MDS is reinverted on
conversion, while MMDS is not.

Sorry, no suggestions for a good use.

73,

Jack WB3U

Much Deleted, due to a nasty newsposter.

More grungy details are in order. This is going into a actual shipping product, so things like transmit splatter, modulation accuracy, lock time are big players. This is also to be powered off of a single AAA cell, so total current consumption is a big issue, also. The actual modulation scheme is a 4 level FSK, with deviation frequencies of +/- 800 Hz and +/- 2400 Hz. The frequencies must be within +/- 40 Hz for the system to work, adding another little bit of Joy.

The current plan is to use a Dual port scheme, where the modulation is appiled to both the reference oscillator and the VCO. My concerns with this is that the parts count starts to go way up, along with the circuit complexity. However, there appears to be no way around it, and no one has suggested any other solutions.

I have perused my synthesizer books, and there appears to be no real mention of modulation in any or them, indicating the appropriate math/simulations to perform. I have MDS (HP's Microwave Design System) to use for simulation, so simulations are another possibility. However, I haven't seen any real detailed treatments of modulation at all, which is why I posted the base message, looking for suggestions on references to track down.

: Rick Karlquist

The original RPG in that generation and earlier actually used a filament bulb as the light source, I think it was only in the mid 80's that things switched over to LED based rotary pulse generators. I'd moved into prod eng for a few years around that time and had to change everything in production at Queensferry over to the new type.

I had a different problem with one... I wore out the shaft and bush in a prototype instrument doing testing (Spurious hunting) I swear one of my fingers is worn down, too. For the gross-overkill-global-domination class transceiver I keep building bits of, I think I may have to make my own RPG with proper ball races...

The mechanical switch things are definitely bad news. Incidentally, how many people know that genuine Microsoft mice use nasty contact type pulse generators? I keep wearing them out playing Doom.

Cheers

I have a lot of old stepper motors from old DECWriter salvage. etc.
I would love to use these, but I do not know the color combinations.

The two different types of motors have either of these color
wires combinations:

or
black red
yellow orange
-- yellow
red ------
gray green
brown
black

(Many of these stepper motors look piggy backed; -- some of the wires
comming out of the top motor, and some from the bottom.)

Is there a standard color coding for these wires? Any guesses?
I can sequence these motors with my computer, but I need a little
more info.

Any help gratefully appreciated!

I would like to buy or build an FM stereo wireless mike: L+R audio inputs,
a range of about 10' and a power supply of 12 VDC or less. Any leads
or assistance appreciated.

You might try your local Kmart or Walmart. I have seen a small FM stereo
tx that they sell. It is desinged to take your portable CD player and
"bradcast" it into you car stereo. I suspect that you could go inside
it and add a preamp to boast a microphone level to a line level.
There might be a "pad" to reduce the level from line/earphone to
approaching microphone level. The mini tx's were pretty cheap..
like maybe $20.00
Good luck and let us know how it works

I have heard about this method but can't find the product.
I believe that the material is run through a photocopier
and then ironed to a copper clad board. Sounds like a quick
way of getting to the etching stage, without having to use
photo-sensitized boards and developer.
Any help would be appreciated.
Thanks.

Jack, it affects you the same way as if one guy drops a 2KW carrier
on 14.313, then 2,000 other hams pile onto 14.313 with 2KW carriers.

Even if you're not trying to use 14.313 at the time, it messes up the band
for anybody anywhere nearby. The bandwidth -- the capacity for the
medium to pass information -- is overtaken by one kind of information that
is not useful to all the users, and is not available to other users for any
exchange of information. It's called "wasted bandwidth" and it squanders a
finite resource.

It probably doesn't affect you DIRECTLY -- except that you might QSY to 40,
or turn on the TV. But until the noise subsides, or the 2,000 copies of the
program get deleted, it takes up more space than it should, space that may
be put to a better use.

Perhaps you're going at this the wrong way. If you want a 4-level
modulation, then perhaps you should be considering a pair of multipliers
in phase quadrature on the output of the synthesizer instead of modulating
it directly. With the appropriate modulating waveform, you can generate
any arbitrary output you might need. The synthesizer is then just a
reference carrier and can be of conventional single loop design.

AFAIK, microwave oven transformers are designed to saturate at the
maggie design current, acting as a crude current regulator and peak
current limiter. This probably isn't behavior you'd want from a linear
amplifier supply.

I'm not sure this would be a handicap so long as the supply was operated below the continuous-rating saturation point. After all, the filter circuit plays a major role in meeting peak power current demands and can compensate for minor transformer deficiencies. Also, given that the used transformers are so cheap, it might be possible to parallel two or three to overcome this shortcoming.

Do you (or anyone) have any specific data regarding the saturation curves of these transformers? Considering how expensive parts are becoming, it would seem appropriate to know for sure whether these transformers are suitable before discarding the idea.

The iron-on transfer method was described in QST last year, I believe.

You should use the clay-coated paper that's specifically for ink-jet printers, and turn up the toner density on the printer or copier.

A caveat -- you have to produce mirror-image art, or it won't work. This means your layout software has to print a mirror image. Of course, there's a work-around. Make a photocopy onto an overhead (clear media). Then photocopy THIS, placed backwards in the copier, onto the inkjet paper.

Then iron it on to the PCB. YMMV, and so far the process hasn't worked for me.

I understand that concept Jim, but I really think it's nit-pickin' to apply it to this situation. If net-wide resources are really a concern, one only has to take a peek at alt.binaries.pictures.erotica and a.b.p.multimedia to realize that a few schematics aren't even a drop in the bucket.

Schematics and other technical drawings would often be helpful and relevant when discussing homebrew topics. Unless objections are based on something other than general resources, I say go for it!

This is only an anecdotal report, not a scientific test.

I used a microwave oven transformer to charge an electric fence.

After 18 hours, resistive losses in the primary had heated the transformer up to about 75 deg C -- past the point of too hot to touch. Still had full voltage, but never drew more than a few milliamperes the whole time.

Resistive heating may be an issue for some builders. I turn my amp off now and then....

All the microwave oven transformers I've seen have been suitable for disassembly and rewinding. So when you need a big filament transformer in a custom voltage, here's where to start rewinding.

Not to dampen your creative spirit, but take it from one who has built many,
many (many) power supplies, etc.....by the time you can buy all of the parts
(including a cabinet to put it in) you can pay for a very nice Astron power
supply....have fun. KN6UG

I agree with Martin with two provisos.

If you have a VERY well stocked junk box the cost can be mitigated. The MOST
expensive parts are the transformer, heat sink, and the case. I have built
projects where the store bought case cost twice what the components inside cost.

The second provisio is that if you get joy from building, then a power supply
can be a rewarding project! They can be as simple as the ones that have a zener
reference and several transistors which provide no protection to the supply or
the circuit being supplied all the way up to fully thermal, over voltage, over
current protected supplies. I have seen several references to ideas in all of
this range mentioned over the last couple of days. I am in the process of
building a design (in the works for a year now) that is at the high end for a
remote packet node for TexNet. Let me know if you still have questions.

Looks like another typical unfounded comment by yet another person in
our government.

Do you think your assinine comment was appreciated by anybody who read your
post, or were you just showing off your mentality? Some people open their
mouth and remove all doubt!

Anyone, especially a child, who shows an interest in something other than
drugs and the idiot box is to commended, not degredated by the like of you.
It's people like yourself that give all the airwaves a bad name, including
amateur radio. With our luck, your probably the sysop of one of those
lowlife, foul-languaged repeaters, that is totally ruining the 2-meter band
for the rest of us.

I have been a licensed CBer since 1957 and a licensed ham since 1959 and
still enjoy utilizing both hobbies and monitor channel 9 on 11-meters most
days for emergency traffic. It's not my fault that the government does not
enforce the very laws they created. If they would, perhaps the illegal
operators would not be as abundant as they are.

Your e-mail account shows you are gaining access to the internet through a
government site. Sponging off the taxpayers aren't you! Why don't you get
a life and leave the kids alone, the only one twisted here is YOU!!!

3539. J.W. Miller IF xfmrs needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-10 00:00:00 UTC
From: RZ5630@waccvm.corp.mot.com
Message-ID: <1995Aug10.182507.15822@schbbs.mot.com>
Source record: 111348

Subject: Millen Xfmrs & other parts

With all the recent discussion regarding the building of "minimum" transmitters, I have gone back to some books I studied in preparation to obtaining my Amateur Radio License. In the 1953 edition of "How to become a Radio Amateur", page 25, there is a four tube superheterodyne radio that I was planning on building back in 1953. The spark has been lit again and I just have to build this radio. I need to find a few components though. If I could obtain the I.F. transformers specified in the construction article, I I can complete construction of this radio. The parts I need are made by the "James Millen" company out of Massachusetts. The parts are:

1500-1600 kc I.F. Transformer, Millen part number 64161
1500-1600 kc BFO Unit, Millen part number 65163
1700 kc I.F. Transformer, Millen part number 62161
Horizontal Oscillator Coil, R.C.A. part number 205R1
Slug Tuned Coil Form, National Radio part number XR-50
Mini-Inductor, Barker & Williamson part number 3008

In the same book, on page 33, there is an excellent 2 tube transmitter that is a companion unit to the receiver. It uses a 6AG7 to a 6L6 to run 30 watts input on 80 & 40 meters. I would like to build that unit also. The only parts I need for the transmitter are the plate coils. They are made by "Bud" and their part numbers are:

BUD OEL-80
BUD-OEL-40
BUD-OEL-20

Some how this station never got built and I think that it would be great fun to complete the project I set out for myself over 40 years ago. Any help you Boat Anchor lovers can provide me, in this personal quest of the Golden Grail, will be greatly appreciated.

Thanks for your help,

Bob, ARS K7NWB

Message-ID: <1995Aug11.171839.47496@cobra.uni.edu>
Source record: 111272

I've been looking for a dual-tone generator to do SSB testing, and FINALLY found one that works very nicely...

Radio Shack 43-145 Pocket Phone Dialer! It's the size of a pager, uses three AAA batteries, and tone 6 is *perfect* for SSB testing. And the bonus you get with this one, hold down two buttons in any row or column, and you get the pure SINGLE tone of that column/row, great for AM/FM testing!

I got mine "as is" at their annual tent sale, but it works OK for me.... My cost was $10, but I 'spose they cost about $40 new, which is well below the price of a test generator, and this is much more flexible in its variety of tones. Appears to be RF-proof, too.

Now if I can just find a cheap sinad meter I'll be all done shoppin' for my test equipment...

From: john@wd1v.mv.com
Message-ID: <john-1108951717400001@wd1v.mv.com>
Source record: 111273

The new Macintosh Ham Test Simulators are HERE!

Novice Ham Test 5.0 SA.sea
Technician Ham Test 5.0 SA.sea
General Ham Test 5.0 SA.sea
Advanced Ham Test 5.0 SA.sea
Extra Ham Test 5.0 SA.sea

The latest versions feature:

HyperCard 2.3 as a stand-alone application (SA) eliminating
the need to have HyperCard. All you need is a Mac with 4
Meg of memory and version System 7 or greater.

Each version 5 Ham Test Simulator has the latest questions
as prepared by the Question Pool Committee.

Each Ham Test Simulator is FREE OF CHARGE and work the
same way as the originals written by Diana, KC1SP.

You may obtain a Ham Test Simulator by mailing me a *FORMATTED
disk (1 per test) and include a Self Addressed and Stamped disk
mailer for the return.

The Ham Tests are now also available via America On Line.

Each Ham Test Simulator is also bundled with a shareware CW
program called MacMorse 1.4 written by Doug, WB0EON.

Also included are a collection of text files that relate an
interesting variety of ideas about the best way to study CW and
prepare for tests.

If you load these onto file servers where others can gain access
via Internet, please let me know so we can point others in that
direction.

Your comments and suggestions for future versions are always
welcome. Stay in touch and good luck with your next test!

73,

>This is only an anecdotal report, not a scientific test.
>
>I used a microwave oven transformer to charge an electric fence.

Good God! Did anyone touch the fence? If are fencing in creatures like the like the ones in _Jurassic_Park_, maybe, but it seems like this would be very likely to be lethal to anyone who gets tangled up in it (If you really want a lethal fence, just connecting it to the 120V line should be plenty. One storeowner got in big trouble with that trying to keep burglars out of the store (or, actually killing one once he did get inside). AFAIK, booby-traps are not legal in the US).

A conventional electric fence puts out periodic very short pulses, enough to shock but not apparently not likely to electrocute. These are usually derived through inductive or capacitive discharge into a ignition-coil type transformer.

>
>After 18 hours, resistive losses in the primary had heated the transformer
>up to about 75 deg C -- past the point of too hot to touch. Still had
full
>voltage, but never drew more than a few milliamperes the whole time.

This is interesting to note. It does make sense that the transformer would be lossy in order to use the bare minimum of iron required.

These transformers seem to be built very much like the "ferroresonant constant voltage" transformers, without the tuned secondary. The primary appears designed to saturate and shunt some of the magnetism through iron blocks installed inbetween the two coils (Anyone ever tried removing those blocks, and making a more conventional transformer out of it?) What is left near the secondary I suppose is constant and independent of line voltage. Some of those ferroresanant transformers didn't mind a shorted output too badly. I have a couple of the transformers but haven't done anything with them yet.

In the microwave oven, the transformer is connected to a half-wave voltage doubler. The magnetron only operates half the time, on half cycles. The RF output is not very clean. Microwave ovens can be detected from hundreds or even thousands of feet away with a good receiver. In an experiment I was involved in, looking for urban sources of noise in the 2.4 GHz band, we could detect them quite readily through several walls and floors of concrete. Measured and computed peak EIRP from a typical oven (although only 2 were studied in any detail) was about 1 Watt. This doesn't seem too

bad considering there is 1400-2000 Watts peak inside, but to say microwave ovens leak only "a tiny amount" isn't exactly right either.

>
>Resistive heating may be an issue for some builders. I turn my amp off
>now and then....

The HV power supply needs to be operating only while transmitting, so continuous duty capability isn't a must although it would save the complexity of switching it on and off.

Whoa! I think you're missing out on the big picture here. It is no simple matter to change the frequency of one of those pagers that much.
BTW, 'cb' is around 30 Mhz...no where near 900 MHz. Next, is the PROTOCOL you intend to use (that the pager expects to see) such as POCSAG or GOLAY
or something equally bizarre. Next, assuming you could tune the thing to the ham band (around 902 MHZ I *think*), you would need a transmitter
at an amazing site cranking-out over 150 watts to get any sort of coverage at all.
Finially, you would need to write drivers to get the email
to bring up some kind of hardware interface to control the transmitter and compress the mail. And actually I think you would have to modify the pager
to get it to take a single message long enough for even a short email message.

Not to rain on your parade, because ideas for things that are not simple are what the hobby is all about but unless you work in paging or an RF field,
(heck, even if you DO) you are getting yourself into a MAJOR undertaking.

If you really want paging, forget alphanumeric; go with an old tone and voice setup and use a voice synthesizer to 'read' you the mail over a voice channel.
Still not simple but you are more likely to finish.

Good Luck

Mark

There is a great book called the Low Frequency Radio Scrapbook by Ken Cornell that gives the details. Actually there are at least two editions, the earlier being tube oriented and the latter tube plus solid state. I think that the Ham Radio bookstore used to sell it and probably Uncle Wayne would have it.

Tip-120s are very common, the NTE number is the generic number for this transistor, usually an ECG number would be the same number. ECGs number is 261.

If you keep parts the way I do, I finally put every transistor in sorted envelopes under the ECG number for that part. That way finding them is easy.

Do not assume that the tools you use to read this apply to everyone.

Anything posted to some groups gets transfered though channels that charge
by volume. Either through people who subscribe to the email gateway list
server and get charged for their email, or by sites that access a limited
number of newsgroups and use the UUCP batching from an upstream site. These
recipients have no option. They get no preview of the traffic. They end
up paying, whether the posting is useful to them or not.

They get really upset if someone dumps a whole lot of traffic on them.
(The most recent case was someone posting a half a meg of cad package
to sci.electronics. Flame city.)

As for a schematic group in the big 7 (now 8) hierarchies, I proposed this
for the reorganization of the sci.electronics hierarchy thats under
discussion now. The word from the group-advice mailing list (who look
out for the interests of all usenet, and more specifically the news
administators) was that it would be considered a binaries group and
should only be a moderated group in the comp.binaries hierarchy. Maybe
you could convince them. I didn't want the hassle, so I took it out
of the RFD proposal.

A single AAA cell? (joy). Certainly there are PLL synth chips
from Motorola spec'ed down to 3V operation, but 1.1-1.5V operation
may be a challenge. I suspect you'll need to pump up a 3V (or more)
supply; there are many parts available to do this. Probably
you'll want to pump up a 6V supply, so you'll have a decent VCO
tuning voltage range available.

What frequency is the final transmitted signal required at?

>The current plan is to use a Dual port scheme, where the modulation is

>no one has suggested any other solutions.

The parts count doesn't change that much for a two-point modulation
scheme. Essentially, you need to make your reference frequency
oscillator into a VXO, which can be done with a varactor or
two and a handful of passives (resistors and capacitors). Keep
in mind you may want to temperature compensate the reference oscillator,
too.

>I have perused my synthesizer books, and there appears to be no real

>to use for simulation, so simulations are another possibility.
>However, I haven't seen any real detailed treatments of modulation at
>all, which is why I posted the base message, looking for suggestions
>on references to track down.

The reference modulation is the same as changing the phase of the
reference; certainly the classic Motorola app note (AN535A) talks
about this. When you modulate the reference, you need to make
sure the loop doesn't pull out or oscillate too much; the selection

of phase comparator is also affected. Note that any of the common Motorola chips will work fine for this as long as you due diligence designing the loop filter.

Kids, please don't try this at home. Modern electric fences are pulsed, to allow a person (or animal) to get away from it between pulses. Older, continuously-charged fences were, I'm told, called "kid killers" because people couldn't disengage due to muscle contractions.

Not true! One way communication is permitted at 70 cM and above (perhaps
on 222 MHz too, I'll have to check). The transmitter has to be controlled
by a ham and the recipient has to be a ham.

I'm not sure about the fine points. There are some "auxillary"
operations that might be ill advised. Also, I can't quite figure out
if the transmitter can be unmanned. Oh well, it might be worth some study!

I know some repeater groups have done this to alert members to turn on
their radios. I would like to know exactly what pagers and how they do it.

I'm looking for some of the Vietnam era military surplus seismic perimeter intrusion alarms. These units were several inches long and about and inch and a half in diameter, had a detachable sensing probe that stuck in the ground, and a VHF whip antenna that resembled a rolled up measuring tape when stowed. They operated on 9vdc. with a power output of 50 - 100 mw. Transmit freq was in the VHF band between 130 mhz. and 150 mhz.

A friend located a few at the Santa Maria ham swap meet this year.

Any info appreciated.

From: royle@emerald.cse.tek.com
Message-ID: <40eanf$mb7@tekadm1.cse.tek.com>
Source record: 111361

This has been an interesting thread, and the comments seem to generally agree with what I've believed for some time:

1. In a properly-designed oscillator with NPO capacitors, the inductor will generally be the dominant drift source. Neither the capacitors nor the active device will contribute significant drift compared to it. This may not be true if the inductor is made very, very, good but was true for all the cases I tried.

2. The temperature coefficient of polystyrene capacitors is opposite that of most inductors. Sometimes you can get lucky and the capacitors cancel the inductor drift (particularly if the inductor has poor drift characteristics). I prefer to first reduce the drift as much as possible by using low temperature coefficient parts, then compensate what's left. This leads to a more repeatable design. The less inherent drift and the less compensation, the better.

3. I suspect but haven't confirmed that inductor drift decreases pretty much as Q increases. Therefore, a good-sized air-core inductor would reasonably drift less than one wound on a small toroid core. (Of course, powdered iron cores also have a temperature coefficient so they further degrade the drift characteristics.) I've done little experimenting with larger air-core inductors but those of you who have, have confirmed this.

One thing I'd watch out for when using air-core inductors is what the field is coupling into. There's a large field surrounding a solenoid. If there's metal nearby, it can lower the Q which may increase drift. Also, nearby material like an epoxy-glass PC board may degrade performance, since this material absorbs atmospheric moisture and has a dielectric constant which is influenced by temperature. It would be prudent to evaluate an oscillator in its final physical form to make sure it works as well as it may have at the breadboard stage.

One other thing to watch for is poor-quality NPO capacitors. Apparently some of the imported ones really don't have low temperature characteristics. An oscillator and can of spray freeze should help you to get an idea of what you've got.

Keep the comments coming!

Greetings all,

I am trying to locate a source of supply of a LM358 IC.
The LM359 is a wideband Norton Opamp and the application is for a video (TV) high gain high input Z amplifier, capable of driving a 75 Ohm unbalanced load, from a single supply.

Despite the fact that it's listed in two local firm's catalogues, they have no stocks. I've tried six local suppliers and one interstate but no go.

It would be much appreciated if someone could let me know a phone No and/or address of a firm who could supply ex stock.

here is a general and specific question. how do I cross reference transistors, chips, etc. I do not want to call up parts stores, because I have so much salvage laying around the house, that I could build a hundred projects, and still not make a dent.

I have a NTE cross ref. program, but that only gives me NTE #'s.

Is there anything more general I could use?

Specifically, this time I was looking for a substitute for a TIP-120 I am sure it is a general purpose switching transistor, but it would have been nice to find some listed as a good cross.

thanks for the ideas.

I see the LM359 in the Digi Key Catalog. 1-800-344-4539.
You might also try the LM6181 current mode opamp which
will drive a 75 ohm load.

I vaguely remember reading that they experimented with intrusion alarms
using bed-bugs. When anyone was in the vicinity and presumably producing CO2
or whatever it is that bed-bugs detect, the bugs got excited and started
jumping up and down. The movement was detected and triggered the Tx.

This reminds me of a story I heard awhile back. Seems there was a company
in South America that wanted to build a Wireless Cable system in their
country. The system would send multichannel scrambled video via microwave
to subscribers, and was designed for omnidirectional coverage in about a 25
mile radius.

Anyway, the U.S. spectrum for this service is 2.5 - 2.7 GHz, but after many
months of wrangling, the operator couldn't acquire those frequencies from
his government. As a substitute, he agreed to use the 2.4 - 2.5 GHz band.

After building the system, he quickly discovered that his -40 to -55 dBm
signals at the subscribers homes were completely obliterated whenever
anyone turned on a microwave oven. Ruined the entire venture.

3574. Broadband Tube-Type KW Amplifiers ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-11 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <808177449.10006@pinetree.microserve.com>
Source record: 111371

About fifteen years ago I came across a transmitter design that has always intrigued me as a candidate for a homebrew project. I was working in the offshore industry at the time and the transmitter was a medium power desktop SSB job with a (then) unusual output circuit.

The finals consisted of four (or maybve it was six) 6146B's in parallel and their output was fed to a toroidal broadband step-down transformer. From the transformer, the 50 ohm output went to a harmonic filter, similar to solid-state designs.

I know some of the commercial manufacturers have produced high-power amplifiers with broadband output networks. However, I'm not all that interested in designing something to match the high imnpedance of a pair of 3-500Z's or an 8877, nor do I want to invest in tubes that costly.

What I have in mind is an amplifier with a relatively low plate impedance and less expensive tubes. Perhaps something like four or six 811A's in parallel, or even two sets of four 811A's, with the power fed to a toroidal combiner.

If anyone has done any experiments along this line or knows the whereabouts of informative articles, I'd appreciate hearing about it.

3575. Modulating VCO's

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-12 00:00:00 UTC
From: dayj@ozemail.COM.AU
Message-ID: <1995AUG12.4436@ozemail.com.au>
Source record: 111284

It seems that the comments in relation to the original posting have concentrated on 'other' methods of modulation, like using DSP's etc.

Generally modulation of a VCO in an FM transmitter is done in one of two ways. But a quick bit of theory.

The PLL uses a filter which is essentially a low pass filter which removes the high frequency noise and variations from the control voltage coming from the phase locked loop controller. The frequencies below the cutoff frequency of this filter are 'within the loop bandwidth'. And any frequency variations detected by the controller wihtin this frequency range will be eliminated.

Every VCO has a 'modulation sensitivity' constant, which is usually expressed in MHz/volt, i.e. MHz of frequency change per volt change incontrol voltage. This value is not necessarilly constant, but can change over the frequency range of the VCO. If a voltage is added to the loop control voltage, simply by summing it resistively is a common practice, then this voltage will cause changes in the VCO frequency. If the modulating signal is outside the loop bandwidth then the mopdulation will appear at the output, if it is within the loop bandwidth then the PLL controller will remove it form the signal and it will NOT appear at the output.

Hence the need for 'two point' modulation schemes. The output frequency of the PLL is directly related to the reference frequency of the loop. This is usually provided by a crystal which is divided down to a much lower value in the IC's. This crystal also establishes the stability and to a large extent the close in frequency domain performance of the loop.

In order to modulate the loop at low frequencies, frequencies inside the loop bandwidth you modulate the reference crystal as well as the loop itself! The higher frequencies are passed to the VCO summing point and the lower frequencies to the crystal. The trick is simply this, you need to carefully design the filters and the level of modulation fed to each point to ensure that their is a smooth transition from the reference modulation to the loop modulation. This can be ab it of a trick!

But all is not necessarilly lost, the need for a single signal to modulate two points is usually found only in high speed data radios, say for 9600bps packet operation. Many commercial radios are two point modulated, the speech or ordinary 1200/2400bps data is fed to the loop modulation point and the low frequency CTCSS or whatever is fed to the reference modulation point.

Yell if you need any further help!

Maybe not as far-fetched as attempts to chemically detect the pungent-smelling "fish sauce" eaten by the VC (as well as most Vietnamese I suppose) to detect when the enemy was near. As I remember (thirdhand), the technology did not work out. I think I have a couple of receivers for an Army intrusion detection system of some sort, they appear to operate on 149.6 MHz NBFM with some sort of digital code. The transmitter part could be excellent for foxhunting if nothing else.

>I need some construction advice on coaxial collinear VHF antennas (you
>know, built out of RG/8 or similar). My references (the 1994 ARRL
>Antenna Book, the 1994 ARRL Handbook and an older ARRL Antenna
>Anthology) are mute on this subject.

The reason they are now mute is the early articles (in QST and the Handbooks) were non-functioning antennas. The problem was the velocity of propagation inside the cable and for the parallel radiating surface currents were different. The phase was changed every 1/2 wl for the transmission line currents but the radiating currents didn't change at the correct phase intervals. So the antennas simply didn't work at all, even though they were published and had lengthy explainations of how well they worked.

Why not build a skirt collinear or a phased stacked dipole array?

>
>A similar technique may exist using GPS as well.

In the MMDS industry, we often have a need to lock adjacent transmitting sites that are fifty miles or less apart to a common reference. By locking the L.O.'s of the TV transmitters and modulators to a common source, we can greatly reduce the visible effects of co-channel interference.

GPS is gaining widespread popularity for this use. When everything is working correctly, there is no actual frequency difference between two (or more) transmit sites, only a phase shift.

GPS receivers used for this purpose include a disciplined 10 MHz VCXO that is updated periodically by the GPS signals. The quality of the disciplined oscillator ultimately has a lot to do with the quality and stability of the 10 MHz output, because the receiver's control pulses only serve to "fine tune" it.

If a custom GPS-locked reference was used directly to drive the counter, it would virtually eliminate the need to ever align it. Cost for these units is still outside the range of the typical homebrew workshop, but prices *are* falling.

I have a freq counter that uses an oddball xtal (3.9 something-or-other MHz.)
What I have is a 10-MHz crystal-oven oscillator and a 100 MHz oscillator
phaselocked to it which will eventually be the base for a 10 GHz SSB
transverter (See Glenn Elmore N6GN articles in Ham Radio.) The 10 MHz
ocsillator is zeroed with WWV.
I use the 100 MHz output to calibrate the freq counter every once in a while.
Makes it a little more accurate than with the 10 MHz signal.

Out of curiosity, is the 100 MHz oscillator a VCO or VCXO? Is phase
noise a consideration in your design?

Now that's a valid reason. Of course, it leads to the question of how to distribute a useful binary. I'm lucky enough to have a personal anon FTP area available through my service provider, but that's not always the case. Also, e-mail can be a real pain if too many folks want a copy. Any suggestions for a work-around, other than starting a new group?

To calibrate to WWV, you zero-beat the frequency counter's reference signal (usually 10 MHz) to the WWV carrier. While listening to WWV on 10.000 MHz, switch on the frequency counter and listen for the beat frequency (Let the counter warm up for a half hour or so before adjusting though). Most cheap counters will leak plenty of signal out that it will couple into the receiver antenna. More deluxe ones usually have a "10 MHz out" or such BNC on the back to which you could connect a piece of wire to serve as an antenna. It takes a bit of time to be sure you really have zero beat, when you are close it will sound like the signal strength of WWV is rising and falling periodically.

This works fairly well, certainly for a quick setup of a counter that isn't going to be very stable anyway. An advanced method I have heard of, but not tried, is to modify a Loran-C receiver to bring out a signal synchronized to the received signal timing. The Loran transmitters are controlled by accurate atomic clocks as well, and being ground wave there is less variation due to the atmosphere. Use a 2-channel scope to compare the average phase drift of the oscillator you're calibrating over the Loran pulse, or simply count the GRI frequency (usually 100-200 Hz). A counter which does "period average" measurements would resolve this low frequency better.

A similar technique may exist using GPS as well. Signals derived from TV broadcasts, once regarded as very precise, are now only moderately precise because the TV stations may resynchronize everything to their local crystal oscillator. This is still better than nothing, and can often be done with no equipment by using a wire or loop "antenna" to pick up and count the horizontal-rate pulses (15.734265 KHz, *not* 15.750 KHz any more) radiated by a TV tuned to a stable broadcast signal.

I've noticed that too. I wonder if the explanation could be that a
larger conductor incurs less IR loss, and is also better able to
dissipate the minute amount of heat that's generated from this source?

Much excellent information has been published on this subject, but I
haven't seen any in quite some time. I think many of the tried and
true principles that used to be applied have been gradually displaced
by the desire to build ever-smaller components. The advent of
synthesizers has also had an effect on the popularity of this
material.

Some of the best information on VFO stability was published in the
60's, a time when VFO builders were still faced with the effects of
tube heat and changing operating characteristics. The same methods
used then still hold true, and solid-state gear can take even better
advantage of them. The trick is finding the info.

73,

Jack

Are you looking for LM 358 or LM 359? you list both in you post.
I have maybe 50 LM358's on hand if that is what you need.

There are numerous cross reference guides. Try and get your hands on as many as you can. Other
common ones are ECG, GE, RCA, and even Radio Shack. I never throw these away, new numbers are
always being added or deleted. The way I figure out whether a part will work or not is by
crossing the number I want to say the NTE number. I look this up and find out what the
parameters are. (ie npn Ic Vbc etc.) Then I check my parts bin for likely suspects and cross
them also. Usually I can find an exact match. Sometimes you can find a functionally equivelant
part with a differnt pinout. If your stuck you can usully twist the leads around to work.
Obviously that won't work with an IC but its amazing what a little ingenuity can do. Generic
chips can often be swapped, but you have to watch the circuit in question. When it comes to
specailty chips your probably out of luck. With transistors, there are dozens of numbers which
have essentially the same characteristics. For instance a 2n2222, 2n4401, 2n3904 are common
npn transistors which are essentially the same. bear in mind that modern silicon transistors
are pretty stable. In a well designed circuit, just about any transistor that as adequate gain,
voltage and current ratings for the circuit should work just fine in 90 plus per cent of the
circuits you are likely to encounter. Well I hope this helps. Stu.....VE7BQy

If you want to detect intrusions for cheap use a 'door-knob' alarm.
You should be able to buy one for less than $10.00.

Instead of 'hanging' it on the doorknob just hook a wire up to the 'hanger'
and remove the resistor for high sensitivity and connect it to the one
for high sensitivity (to make it MORE sensitive - figure it out for _YOUR_
particular model with a resistor break-out box).

Run the wire around the yard (insulated and buried one inch).
Tape the alerter to make it quieter (mine was so load the person would
have heard it !).

Be aware that the sensitivity _IS_ critical to prevent rain or large trucks
from changing the field and setting it off falsely.

Use two or four to "zone" yourself and place them in the corner of the
room representing the 'zone' (direction) the intrusion comes from.

Works great ! - After a few 'falsies' the cats (feline animal) 'learn'
to avoid setting it off (and your wrath) so false alarms will decrease in
a day or two. Rain _really_ is your WORST enemy, just take the _single_
wire and pull the insulation on the end while sucking some crazy glue
into it and tie it to ensure no leakage - the system will stabilize one
the soil does. - No cheaper or more effective method (even infrared or
ultrasonic units from Radio Shack are worse (for falsies and price - and
cats are not trainable for them as easily as a buried wire for some reason)).

> . . .

This stands to reason. Everything else being equal, a higher-Q inductor will generate less heat than a lower-Q one. But all else is seldom equal. The effect of heating is to change the physical dimensions of the coil, which in turn changes the inductance. I would imagine there could be quite a difference in inductance change as a function of temperature depending on the shape of the inductor and the expansion characteristics of the form, if any. Also, as you mention, the amount of temperature rise which results from the heat depends on the heat sinking/dissipating ability of the coil.

Hmmm. . . wonder if a shape could be found such that the inductance is constant if all dimensions change in an equal ratio. I'm sure somebody thought of this a generation or two ago. . .

I am pleased to announce a new product offered by Positive Time Systems called the RCS-I. This is a radio controller that connects to any VHF/UHF transceiver and can issue x-10 commands. (X-10 is a power line standard for controlling devices throughout a building. Sears, Radio Shack, and others offer these compatible units)
The unit also has an alarm input, a listen feature, a short voicmail box, and responds to all commands in a pleasant female voice. The system IDs with your recorded voice and call sign. This description doesn't do the product justice, so please check out the new homepage at :

http://www.halcyon.com/pos.time.sys/top

or you may email us with you address so that we can promptly send you our brochure and newsletter.

NOTE: This product is intended for US voltages of 120 / 220 VAC. Another version is offered to support other international power standards.

FLASH! NEW FEATURE! The RCS-I has a new feature called Secure Access Mode(SAM). When enabled, the access code changes dozens of times per hour, making it virtually impossible to hack into.

Thank You,

Marshall Craw <mcraw@halcyon.com>
Positive Time Systems
North Bend, WA

>calibration can be done with a home made IE: inexpensive freq. standard
>in the shack?

There are two rather simple ways to calibrate a counter against WWV.
First, if your counter reference oscillator's fundamental or harmonic
falls on a WWV frequency, then you simply use a receiver to zero beat
the reference to WWV. For example, if your counter uses a 10 MHz reference
oscillator, you'd just filch a bit of that signal out of the counter
and inject it into your receiver along with an antenna input for WWV.
Put the receiver in AM mode, and adjust the reference oscillator for
zero beat, a scope can help when you get down to a subaudible beat,
or you can watch the S-meter's rise and fall.

If your counter's timebase isn't a fundamental or harmonic of a WWV
frequency, then you'll need a transfer oscillator. A 10 MHz crystal
oscillator will do. Just zero beat it to WWV with the receiver as
above, and while it's at zero beat, read its frequency with the
counter. Adjust the counter's reference oscillator so that the
counter displays exactly 10 MHz and you are done.

Needless to say, the counter should be warmed up and stable before
attempting this calibration.

3608. Using ZN414 to receive SSB

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-14 00:00:00 UTC
From: ian.mitchell@research.utas.edu.au

Source record: 111172

Hi,

I'm trying to design a general coverage receiver using
the MC3362 from motorola. I'd like it to receive AM, FM
and SSB/CW signals. FM is built in, and I'd like to think
I can use the ZN414 for AM, by tapping in to the signal
at the output of the second IF filter (455KHz).

The ZN414 is essentialy an RF amplifier and detector with
built in AGC. The problem is how to resolve SSB? Generating
a 455KHz BFO is no problem (using TTL levels), and can be
arranged to switch on and off via uP control.

I am hesitant of providing a direct BFO signal (not TTL) to
the ZN414 for fear of overloading it.

I thought of using the BFO signal to switch the SSB signal on
and off at 455KHz. Another 455KHz IF filter would be used
to reduce harmonics, just before the ZN414.

The question is, would this work?

Best regards to all, Ian

>
>KW>Thanks for the info... Kevin N1EPU

There are simple circuits for detecting the off-hook condition. For
example, in _The Talking Telephone_ (Tab Books, 1990). Kits are
also available, often at hamfests. These use a separate 9V battery
since the phone company frowns upon users lighting their homes off
the phone battery.

I solved this problem by having another phone line installed. The
inconvenience to my net habits became much less important than the
amount of time I tied up the phone so others could not use it.

I'm not familiar with the specifics of the ZN414, but the built in AGC might be the most difficult problem. If it's keyed to the detector, you may have a difficult time keeping the BFO from activating the AGC and reducing receiver gain.

Bob (K7NWB) was looking for 1500Khz to 1600 Khz IF transformers.

Bob:
You may have trouble finding the exact parts. (BTW back then they wer
1500 Kc transformers :>)). The Heath HR 10 series of receivers used this
frequency as the IF with a very broad 2 crystal half lattice. You could try to
contact Heath and see if they still have any repair stock left. Another
alternative if you don't care about exactly the right parts woulfd be to find an
old NON-FUNCTIONAL BC454 or BC455 .(PLEASE, PLEASE, please don't destroy a
perfectly good working piece of history). These radios also used an IF in that
range. They also came with a variable BFO, a fact I learned when going through
some 1960's era CQ magazines.

Good luck with your project. It sounds like fun.

Back in the 1960s the ARRL handbook (and old SSB handbook) had a 4cx1000
anp and the Collins 30S1 of similar vintage also used one.
You can get ap-note from Eimac in Utah which has the same articles.
The 4cx1000/1500 makes a dandy linear amp!

You can also use a standard 'lead' (graphite core) pencil. Attach a wire at each end where you expose the core (alligator clips?). The amount of resistance will vary with the graphite core length, density, diameter. You can increase the resistance by filing through the pencil more or less in the middle but just don't cut all the way through the core or you've ruined it.. The deeper the cut into the graphite core, the higher the resistance, BUT, you will lower the amount of power it can dissipate at that point. The assumption here is that you have some means of determining the resistance as you file into the core if you are concerned about a specific value such as 600 Ohms.

10 COMMANDMENTS FOR TECHNICIANS

I. BEWARE THE LIGHTNING THAT LURKETH IN THE UNDISCHARGED CAPACITOR, LEST IT CAUSE THEE TO BOUNCE UPON THY BUTTOCKS IN A MOST UNTECHNICIAN-LIKE MANNER.

II. CAUSE THOU THE SWITCH THAT SUPPLIETH LARGE QUANTITIES OF JUICE TO BE ONPENED AND THUSLY TAGGED, THAT THY DAYS IN THIS EARTHLY VEIL OF TEARS MAY BE LONG.

III. PROVE TO THYSELF THAT ALL CIRCUITS THAT RADIATH AND UPON WHICH THOU WORKETH ARE GROUNDED AND THUSLY TAGGED LEST THEY LIFT THEE TO RADIO FREQUENCY POTENTIAL AND CAUSETH THEE ALSO TO MAKE LIKE A RADIATOR.

IV. TARRY NOT AMONGST THOSE FOOLS WHO ENGAGETH IN INTENTIONAL SHOCKS FOR THEY ARE SURELY NONBELIEVERS AND ARE NOT LONG FOR THIS WORLD.

V. TAKE CARE THAT THOU USETH THE PROPER METHOD WHEN THOU TAKEST THE MEASURE OF A HIGH-VOLTAGE CIRCUIT LEST THOU INCINERATE BOTH THYSELF AND THY METER, FOR VERILY, THOUGH THOU HAST NO ACCOUNT NUMBER AND CAN EASILY BE SURVEYED, THE TEST METER DOTH HAVE ONE AND, AS A CONSEQUENCE, BRINGETH MUCH WOE UNTO THE SUPPLY DEPARTMENT.

VI. TAKE CARE THAT THOU TAMPERETH NOT WITH SAFETY DEVICES AND INTERLOCKS, FOR THIS INCURETH THE WRATH OF THY

SUPERVISOR AND BRINGETH THE FURY OF THY SAFTEY INSPECTOR UPON THY HEAD AND SHOULDERS.

VII. WORK THOU NOT ON ENERGIZED EQUIPMENT, FOR IF THOU DOST, THY FELLOW WORKERS WILL SURELY BUY BEERS FOR THY WIDOW AND CONSOLER HER IN OTHER WAYS.

VIII. SERVICE THOU NOT EQUIPMENT FOR ELECTRICAL COOKING. IT IS A SLOTHFUL PROCESS AND THOU MIGHT SIZZLE IN THINE OWN FAT FOR HOURS UPON A HOT CIRCUIT BEFORE THY MAKER SEE FIT TO END THY MISERY.

IX. TRIFFLE THOU NOT WITH RADIOACTIVE TUBES AND SUBSTANCES LEST THOU COMMENCE TO GLOW IN THE DARK LIKE A LIGHTNING BUG AND THY WIFE HAVE NO FURTHER USE FOR THEE EXCEPT THY WAGES.

X. THOU SHALT NOT MAKE UNAUTHORIZED MODIFICATIONS TO EQUIPMENT, BUT CAUSETH THOU TO BE RECOREDED ALL FIELD CHANGES AND AUTHORIZED MODIFICATION MADE BY THEE, LEST THY SUCCESSOR TEAR HIS HAIR AND GO SLOWLY MAD IN HIS ATTEMPT TO DECIDE WHAT MANNER OF CREATURE HATH MADE A NEST IN THE WIRING OF SUCH EQUIPMENT.

3621. How to Space-Wind Coils?

From: jackl@pinetree.microserve.com
Message-ID: <808363044.19680@pinetree.microserve.com>
Source record: 111320

The other day I was in a sporting goods store and noticed
that monofilament line starts at a diameter of about 0.005" (2 lb
test) and goes up in increments of about 0.002 or 0.003 from there.

This is close to the size of many common wire gauges and I'm wondering
if anyone has ever used fishing line to space-wind a coil? I know the
diameter of different brands will vary, but is it reasonably
consistent throughout the same spool? For my purpose, the exact
spacing is less critical than the need for it to be consistent from
one end of the finished coil to the other.

Thanks & 73,

Jack WB3U

3622. Re: KENWOOD IF-10D Interface WANTED

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-14 00:00:00 UTC
From: ibmdelf@aol.com
Message-ID: <40mjhc$md2@newsbf02.news.aol.com>
Source record: 111321

I built my own interface using just a MAX232 chip and four 10uF caps. However, before diving into this project I had read somewhere, and verified for myself after connecting the TS-50 to my computer, that several of the control features found in other Kenwoods are missing from the TS-50. The most serious omission is the capability to write a frequency to any of the memory channels. Any of the Kenwood control programs I've ever used would be crippled when used with this radio. All of the programs allow you to read and write frequencies to the memory channels in Kenwoods that support this. This would allow you to have several "pre-load" files with frequencies to program into your radio. For instance, if you have 100 freqs for SWBC, just load the file and the memories are reprogramed in seconds and you're set to go. Have another file for aero-traffic on the SW bands, etc. The TS-50 does not allow you to do this. I was very dissappointed when I confirmed the crippled nature of this radio. About the only way around this may be to write a program that provides "virtual memory channels" which you select from your computer screen and it will write each virtual memory channel frequency into the 'A' or 'B' VFO as you select different 'virtual memories' on the computer screen.

A point of observation: I have the service manual for this unit and in the block diagram of the system, where a computer and RS232 interface connect to the 'digital board' in the radio there is a notation: "For factory and debug". That just about sums up Kenwood's reason for building it in. It certainly wasn't included for full remote-control usage by the owner. I guess Kenwood just couldn't imagine anyone wanting to connect a computer to a mobile unit. Don't you just love how the manufacturer looks out for you?

On an up note: this radio is a fine piece of gear, particularly for mobile work. I've mounted it in the console right below the AM/FM/Tape factory radio and it blends well. I do miss a notch filter such as the one on my TS-440 though.

I have made some mods to it including restoration of full spectrum transmit capability which for me serves two purposes: a test signal into a dummy load when aligning other gear including the TS-440 and for use on the CAP bands.

If you would like a copy of the MAX232 schematic as it applies to the TS-50, drop me a note. Although I have drawn the schematic in .BMP format, I cannot upload it onto the Internet from my access point so I would have to mail the hardcopy to you.

I also have one for the TS-440 if anyone is interested. The TLL signals of the two radios are NOT the same so if anyone was thinking of using the

same one for both, forget it. You have to build an interface with a hex inverter added to the MAX232.

There should be absolutely no place whatsoever for this in QST.
The software is as much a part of the project as the PC artwork
and the bypass capacitors. We must rise up against this kind of
tyranical nonesense and put a stop to it! It is OK by me if the
company wants to buy 4 full pages of advertising to push their
proprietary designs in the form of a product. It is in no wayh,
shape or form suitable for editorial material in QST to contain
proprietary software.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

I haven't had much luck with it either. I seem to end up with
uneven density of toner on the traces and other copper areas. I've
tried it both with my HP laserjet, and with a standard office
copier. The other problem that I had was patches (both small and
large) that didn't attach to the copper clad when I transferred the
pattern. I sure would like to see an easy way to get the resist
pattern onto the board.

Could an audio amplifier be used as a VLF receiver???
Antenna, diode and a capacitor hooked up to the input???
Broadbanded yes, but will this work? Frequency is from dc to
15 KHz. Opinions/comments/suggestions welcomed as to any
schmatics.

There are several FTP-by-mail servers around the country (and around
the world). It's not instant gratification, but I can say from per-
sonal experience that they *do* work for people downloading files.

For all the gory details, scan news.answers for the "Accessing the
Internet by E-mail" FAQ. That's not the exact title, but it's some-
thing close.

3636. Power Good line on PC P/S

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-15 00:00:00 UTC
From: Jim Strohm <jstrohm@blazer>
Message-ID: <40qv88$s0e@unisql.unisql.com>
Source record: 111195

Hi

I want to use a surplus PC power suppply to power some non-RF ham goodies.
What signal does the Power Good line need to see to turn on the power supply?

Does anybody have a simple schematic to provide this signal?

Please don't suggest a motherboard -- I already have an XT and an AT
motherboard I can use, but I consider it overkill.

TIA
Jim N6OTQ

David - KB4LCI
dgordon@nrao.edu<<<<<<<

David, Actually the diode would be un-necessary if your hearing was very good! The problem is that buzzes from power lines, whistles and pops from lightning, and all kinds of other junk would wipe out what you wanted to hear, so you would need an input filter.

Unless your ears are better than mine you would need to convert that 15 kHz to a lower tone to be comfortable with it!

>Hi
>
>I want to use a surplus PC power suppply to power some non-RF ham goodies.
>What signal does the Power Good line need to see to turn on the power
supply?

The Power Good line is an *output* from the supply, which indicates to the
PC that it is supplying good power. It is used to reset the CPU during
power-on, and also to reset it in case the input voltage drops or something
else goes wrong. The line is TTL compliant, high while power is "good" and
low when it is not.

Most cheap clone supplies only supply a short pulse at power-on. The ones
built to IBM specifications would generally have a more elaborate circuit
to compare each output voltage to what it should be, and output the power
good signal only if all were OK.
>
>Does anybody have a simple schematic to provide this signal?

You can leave it unconnected. The supply will operate without a load on
it.

What the supply will often not operate without a load on is the +5V output.
This is probably why you couldn't get it to work without connecting a
mother board. The supplies regulate the +5V output, as this is the only
critical one for the computer. If that output can't be kept in range, the
supply will shut down. The other outputs are proportional to the +5V
output by virtue of the ratio of the turns on the transformer.

So what you need to do is either modify the supply so regulation is based
on the +12V output (which would also be good since you could then turn it
up to +13.5 V or so to possibly get better radio performance) or,
less optimally, but not requiring modification, provide a load of about 1A
on the +5V output. Some may require even more loading before the +12V
output will be capable of its full rating, and again that output is not
directly regulated so it can vary 10% or so. These supplies are designed
primarily to supply +5V. The other voltages are sort of "along for the
ride". But you can power a few small radio devices off of one if nothing
better is available.

The *best* antenna would be a dish the size of a radio astronomy
telescope. You could expect to put the transmitter on the *moon* and
still be able to hear it from the earth.

I expect though, that that is out of the question. There are many
variables to be considered. Give me a personal E-mail message and
I'll try to help you sort them out.

Jim "With an FCC licence." Meyer <jimbob@acpub.duke.edu>

P.S. It would make reading your messages easier if you could find out
how to make each line average out to about 70 characters in
length.

3644. Inductor coil

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-16 00:00:00 UTC
From: root@localhost.com
Message-ID: <40rtad$187j@msunews.cl.msu.edu>
Source record: 111203

Hey...I'm building this Radio and I chipped about 20% off of the
inductor coil that screws into this metal silver box. The RF signal quality
is pretty bad, and I'm associating it with the chipped coil. I've reordered
a new one, but it seems odd to me that it still works with the chipped coil.
should there be much improvement with the whole coil intact? I don't really
know much about how this thing works (all I know is that it tunes the freq.)
and I don't know what quality signal to expect. If someone could explain
this inductor coil for me...
thanks

3645. RF amplifier

Newsgroup: rec.radio.amateur.homebrew

Source record: 111204

Does anyone know how to make a cheap RF amplifier? I got this schem
out of radio shack, but haven't tried it yet. It says it will increase the
signal by 2x.
its:

```
|
| 9v battery +
=
= 1k resistor
|-------------------------> signal + out
-----
1uf cap| D
------|---| 2N3819 transistor.
+ in | S
------
-----------------|-------------------------> signal - out
- in 9v battery -
```

Sorry for the crappy schematic, but will this work?

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
August 20th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

The reason I am interested in the coax version is I have a surplus
150Mhz whip
that I think is a coax collinear inside (I x-rayed it!)
Before I start hacking it apart to get is to work on 146 Mhz
I thought I would try to get some info on the theory.
I could, of course, just hammer-and-tongs the project by starting
at it with a saw but...

Anyway, that's why I wasn't considering some of the other types
of antennas as they would not fit inside the hollow mast.

I have a very noisy line today - sorry if there are garbage
characters!!

Those circuits usually use a 11C90 which is an ECL circuit with TTL interface,
if I am correct.
Does anyone know who sells that chip in small quantities as well as the Harris
(Intersil) ICM7216 series chips?

Thanks, Peter

A circuit for a 48 MHz TX unit has been uploaded to
http://www.cf.ac.uk/uwcc/suon/radio/badger.gif

PLease could you take a look, and tell me what you think?
The circuit is a 12 MHz crystal osc. followed by a tuned buffer stage,
two doubler stages and a driver stage. Output is from the wire that
disappears off the right hand side of the screen.

The values of the inductors is not included on the diagram. they have
been calculated to be resonant at 12, 24, and 48 mhz as
appropriate.
The inductor in the driver stage is made up of three white Toko S18 air
cored coils in series

Thanks in advance

Andrew Webb, GERME

Go to your local branch of WH Smith and buy a copy of the Cirkit catalogue.
Cirkit stock most of the Toko range, and you'll find the S18 parts in
the catalogue. If you have problems, phone Cirkit on (01992) 448899.

Any kind of phase modulation (versus frequency modulation) is
going to have inherent pre-emphasis and very poor low frequency
response. For sending baseband data (such as 9600 baud GMSK),
these are both disadvantages. For sending voice or audio
modulated data (such as 1200 baud Bell 202), this is fine.

Not likethat it won't. you will need a resistor from gate to ground, maybe a few hundred k ohm and a parallel capacitor/resistor from the source to ground (or - battery) of a few k ohm and few thousand picofarad.
You would be better to use one of the little broadband amps from Mini-Circuits that sells for a few bucks unless you are somewhat familiar with FET designs.
Regards, Al

You can unsolder it and connect it to a signal generator and excite
it at 10 MHz. A regular diode (assuming it's not a power rectifier
type) should have little trouble recovering in the 50 nSec. available.
A PIN diode will have a very long recovery time and be unable to
rectify the 10 MHz. Compare to a known reference like a 1N4148
switching diode.

> Sorry for the crappy schematic, but will this work?

It will work even better if you replace the 1k resistor with an inductor/capacitor tuned to the frequency of interest, or just an inductor if you can't find one of those cute little variable caps that look like jelly beans. Depending on your frequency of interest, you might start at an inductor value with a reactance of 1kOhms at that frequency. For example, at 10 MHz, the required inductor value would be about 20 microHenries. The C to resonate at that frequency would be about 20 picoFarads. IF you stay at 1k Ohms, you can scale to other frequencies.

You will also need to run a high value resistor to 9V minus from the gate of the FET for it to work; about 100K or more Ohms (very uncritical).

Furthermore, the 9V minus supply is not strictly necessary if you make that ground instead of minus. The extra 9V gives you more range for large input voltages without distortion, but is unnecessary if you are only interested in milliVolts or less.

3665. Phone Line Status Indicat

Doing this is indeed an excellent idea. However, one needs to remember that oftentimes the NTE part may have significantly higher ratings than the original part. For example, the 1N4001 through 1N4005 diodes crosslist to the same NTE part (NTE 116), which w/ its 600 V PIV rating can be used as a single substitute for these JEDEC parts. Having a bunch of 1N4001 through 1N4005 parts in a bin marked "NTE 116" is OK, but mindlessly grabbing a 1N4001 out of the bin for use in a circuit where a 400 V PIV rated device is called for could result in a failed circuit. My point is, be aware of reduced component ratings if you mix together a bunch of different parts in a bin. You could try segregation of parts within your bins (through bagging or other means) to help prevent putting a "runt" part in a circuit.

As another poster suggested in this thread, there are other crosslisting resources available. I've used NTE, ECG & SK cross reference guides for years, and I've also used the old Raytheon REN and Motorola HEP guides as well. Sams has published transistor substitution books in the past, and I'd recommend getting your hands on one. There's a shareware tool for IBM PCs called SCRL (can't remember the exact name corresponding to the acronym @ the moment); I believe you can find it on the SimTel mirrors or on other ftp sites - look for a file named scrl50.zip. Sometimes, old manufacturers' databooks can be useful - for instance, the mid '60s Motorola databooks had a fairly complete listing of 1N & 2N parts (for that time), the minimum characteristics of each JEDEC part, & some Motorola recommended substitutes for a given part. Some databooks (such as Siliconix and old Sprague books) give good clues to devices which share a common fabrication process, and could be an alternate cross reference

source. You might also consider getting your hands on some Japanese transistor specification books, such as the ones MCM Electronics has sold periodically; such books may be the only way to get device ratings for a 2Sx part if you can't find it listed in the usual cross reference guides.

It's even simplier than that. As I recall I did it by opening one circuit trace on the bottom
of the motherboard. Off hand, I don't remember which one, but I'll dig out the manual (it's in my storage room) when I get over my cold. If you don't get another answer, email me to jog
my memory, cuz this newsreader trashes things sometimes.

From: pff@bfs.uwm.edu
Message-ID: <pff.15.000D283B@bfs.uwm.edu>
Source record: 111233

I am having trouble with an amplifier I have built per motorola application note AR313. The trouble is the MOSFET conducts (drain to source) when no gate voltage is applied. This is not supposed to happen. This happens regardless of the configuration the gate is in. By this I mean the gate is not supposed to float or be left open at any time. I ground the gate and the devive still conducts! I have checked and rechecked the circuit and all components two dozen times. I have compleletly disassembled the amp and put it back together a piece at a time testing the circuit at each step of the process. It still conducts. The device is not completely turned on as it draws about 700ma. Several other strange things are occuring. When I turn the power off my amp meter still shows the device drawing about 5ma? Stranger yet is that this 5ma draw seems to change with respect to the amount of sunlight hitting the device? When shaded the current draw drops to around 2ma. This is a very simple design and should be easy to build. I have had nothing but trouble. The only thing I can think of is that I am going about testing and setting the idle current all wrong. Does the device need to have input and output loading on it when setting idle current? Or in any testing? Any help would be greatly appreciated.

The copper has to be *clean*, I mean *really* clean, and the iron
has to be at the right temperature (cotton high, and use a cover
cloth and a lot of pressure).

We got a laser printer for home use a year or two ago. I got "demo"
pages from several brands at the local computer stores, took them home,
and tried ironing them to a PC board.

There was a wide variation in how well the toner sticks. The cheaper
Brother laserprinter was best.

With the quantity of knowledge and the buying power of this group, we should send a letter to a company like Motorola, Radio Shack MCM electronics etc., and ask them if they would found a web server to store, post, schematics, they could also advertise their parts, new products etc. after all they already have an Internet connection (I�m assuming) they would only need a server. Any Ideas

Really, you can only tell by part number. It is unlikely that any but the most recent receivers would have PIN diodes. They are a bit more expensive.

Could you post a little more information on this. Do we need to load it with a resistor? Can we just hook it up to a multimeter and see if the RF is detected and varries as we move the signal gen level up and down? It sounds too easy....We all want to make it diffucult.

There is a very complete article on this in this months issue of "Nuts and Volts". The author is sold on it but has went to some expense in setting up. There have been some good discussions on this is sci.electronics over the past few months. Many swear by it and some swear at it. I have no experance but from what I have read would give it a try if I had a laser printer.

Garry

PS
I've found many reluctent to allow anyon eto stick strange stuff in thier printers/copiers.

If you are aware of the illegality of their use, why do you still want to build one.
These were outlawed many years ago for good reason. The reasons are even "gooder" today.

Please consider the unintended consquences of using one of these and find another project.

Maybe you could explain "your" theory. <g>

Sincerely, Wes -- N7WS

My experience was PIN diodes have about 1 volt forward drop, while regular
silicon signal diodes have 0.6 volt, while Germanium and Schottky Diodes
have about 0.3 volt.

One other method that works well is to build a simple 10 Mhz
oscillator with a buffer stage. Use a T coax adaptor on the
output to drive a piece of wire for the WWV rcvr, and a direct
connection to the counter. Zero beat the oscillator, easier
brecause of the stronger signal, and adjust the counter when
audio beat is no longer flucuating (watch S-Meter on rcvr.)
This method will allow you to input a signal directly to the
counter on any range input, and adjust even the divide by
256 prescalers (3.90425 Mhz crystals).

If it's a low wattage unit and not connected to an antenna then it's
not illegal to operate. Various vintage radio groups will fire up
their sparkers occassionally to make recordings to send to members and
such. The California Wireless Society made such tapes `off-the-air'.

George: The best place to start would be to check a college library.
Here at UH we have a wealth of info about the history of radio,
with many books written by the famous pioneers themselves.

Source record: 111254

Having operated a "LowFER" station for several years, I might make a comment or two on 'interpretations' of the part 15 rules.

The rules actually limit the antenna length to 50 feet (I can't recall if it's given in feet, or as a metric length, but that's close enough...)

The was this is interpreted by most LowFERs is a 35 foot mast, with a 15 foot radius tophat, or something along those lines.

With the "typical good" Lowfer transmitter station, the radiated power (with 1 watt "input to the PA" (which can translate to about 960 milliwatts or so with a WB7CAK-type transmitter...) will likely be in the 1 milliwatt region, although 'CAK *did* acheive an efficiency of approximately 1% - but after doing things like having a heavier-guage Litz-wire lo
ading coil, auto-antenna tuner, etc.)

Officially, the FCC "frowns" on using amateur calls on non-amateur frequencies, but I don't think that it is necessarily illega
l. Use of them in leiu of the
appropriate call for that frequency/service would be illegal, of course. Many LowFERs use some portion of their ham call as th
eir LowFER call (i.e. 9HDQ, or
8LXJ) such that one could logically determine the operator.

As for receiving LowFER stations, I have just used my Drake TR-7 along with both an Active whip, and a loaded random-wire (an HF-antenna with a TV-horizontal oscillator coil in series, tuned for resonance) and from a previous QTH (Flagstaff, AZ) I have heard a number of California LowFERs, as well as 9HDQ and 8LXJ in Indiana and Ohio, respectively. I could reliably hear the better-equipped California LowFERs almost any night the static wasn't too terrible...

>
>George N7BUI
>
and then the readers of rec.radio.amateur.homebrew (with a few exceptions) responded with a barrage of flames. On first glance, three things about the post suggest it is worthy of flaming:

* Use of a handle ("Einstein") rather than a real name. However, on closer inspection, a real (first) name and ham callsign are given. N7BUI has been issued to an Oregon resident named George. It is of course hard to prove that he is the actual writer of the post.

* Explanation that the intention was a "science project". Many times this is used to conceal actual intentions. However, I would consider a spark gap transmitter (unlike a "K3Wl BoMb") an interesting piece of scientific history that would make a good science project. Many sets of plans for the various types of spark gap transmitters are likely to be old and of historical interest as well.

* "I know they are illegal to use," but... Come on guys, it is obvious they are illegal to use. It would most likely only be used for a brief short-range (limited power, no antenna) demonstration, if at all. If one is even built. A study of the various designs and an interpretive presentation of the advances in this technology would be a credible science project, without actually building a working transmitter. If he wanted a practical radio transmitter or jamming device, one using more modern technology would be much more suitable.

Since I'm not familiar with spark transmitter technology (although I'm now at least a little informed after reading Tom's and some of the other responses), I can't directly answer George's request. But I did want to comment on the knee-jerk negative reactions I saw from many.

Motorola already have such a site. Try http://www.mot.com. If you browse through the links, you can find some useful stuff, e.g. at http://motserv.indirect.com/cgi-bin/dlsrch there is a form which allows you to retrieve data sheets by part number. (Not complete yet, but lots of stuff) As a test, I just downloaded the data for MRF174. It's essentially identical to what's in the RF Device Data handbook - specs, graphs, Smith charts, the lot. (But a bit slower than flipping open the book, if you have one :-)

: Jim N6OTQ

Just something to watch for....

I had a friend who ran a 145MHz rig from an Ex-computer PSU. Due to the rather poor filtering of the output of the switch-mode PSU, he came out every 20Khz or so over the whole of 144 to 145Mhz (and probably more either side of the band).

This was about 10 years ago, so PC-PSUs may be better these days!

Sounds like the gate has somehow been shorted to the drain. The device has thousands of gates (and transistors) in parallel and if a few of the gates get shorted to the drain due to ESD, the condition you see will exist. You could (carefully) check with an ohmmeter between gate to drain or source and if there is any resistance value less than infinite, you may have killed the part. Despite the fact it is a 'power transistor', MOSFETS are ESD sensitive and can be all too easily damaged.
If you cannot measure any reisistance less than infinity on the highest range, try a putting a few (<5) volts negative on the gate and see if the current will diminish. It's very rare but sometimes a contamination can shift the threshold down.
I think the device is woulded. Sorry.

In your not so humble redundant opinion. (Are you a lawyer BTW?)

Perhaps this medium isn't the best way to offer what was intended to be constructive advice.
The point most of us (I think) were trying to make is that careless operation of this thing could be a problem. I obviously don't know George and HE certainly hasn't given me reason to
be insulting. If you read this group often, you will note many questions which are coming from
inexperienced individuals (not I said inexperienced, not stupid) who are attempting to do something inappropriate. Perhaps it's my "Elmer" nature of wanting to help, getting me in trouble with you. Frankly, it doesn't matter.

I really doubt that the intention was to use four foot diameter coils and operate in a Faraday
cage. When the man says "I know it's illegal but... I want to do it anyway", what does it say
to you? I was and am trying to dissuade George from radiating a signal with this device.

: George N7BUI

George then got soundly flamed for even suggesting building such a horrid thing. It seems to me from the responses I've seen that more people _should_ build spark transmitters, so that others could gain a better understanding of just how they work. A good spark transmitter is NOT just an EMP generator that puts out seeminly unlimited power on all frequencies at once. Spark transmitters were generally used on low frequencies, where a tank with a loaded Q approaching 100 could be rather narrow-band. The spark itself does not generate the transmitted energy: the spark is a switch that completes the tank circuit in a very low impedance way. If you couple to that tank with additional filtering (multiple coupled tuned circuits), the result can reasonably be a signal with a very few percent bandwidth, or even less, and if you don't care about efficiency, it should be possible to generate signals that have a bandwidth not a whole lot worse than AM on the 75 meter band. To do that, expect to use BIG coils with very carefully designed shielding. (A helical resonator on 75 meters??!! You can apparently get an unloaded Q in excess of 5000 with a 4 foot diameter shield.)

There has been a series on spark transmitters in the British magazine "Electronics and Wireless World" recently. I haven't followed all the articles, but those that I saw were enlightening. Consider that spark transmitters that generated a significant fraction of a MEGAwatt were used to communicate on VLF between the South Pacific and Europe, and the bandwidth was in the kilohertz range.

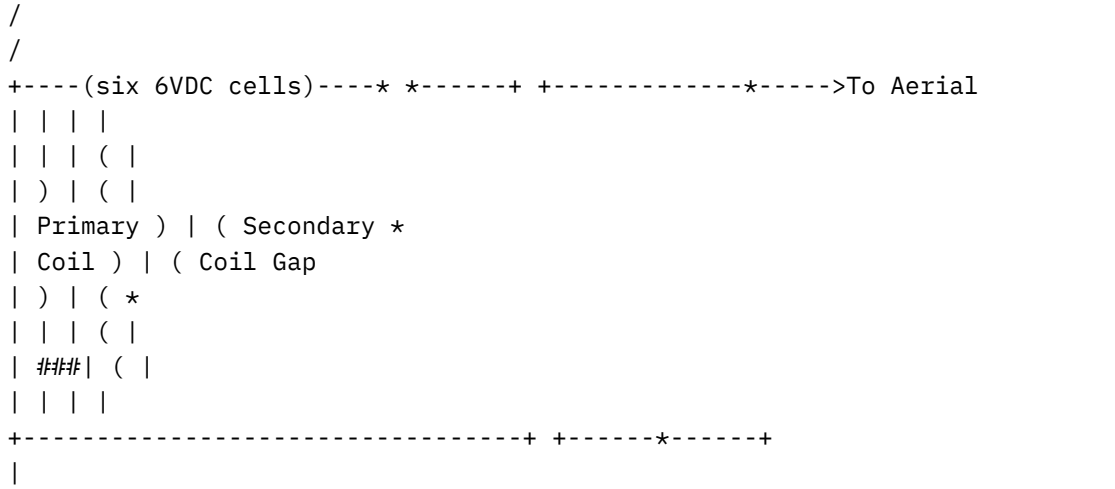
Umm, Dana, if we restrict the power lever to that required to fire
the spark plugs on your motorcycle, then we'll satisfy Part 15. (Have
you checked your bike for Part 15 compliance? ;)

My `blanket declaration' mentioned low wattage with no aerial. A
potentiometer in series with the primary coil will allow the operator
to find the minimal voltage needed to fire a spark across the
electrodes' gap, and we'll want to keep that gap very small. Field
measurements can then be taken to insure compliance with Part 15,
while increasing the voltage across the primary coil.

The previous poster made it sound *completely* illegal to operate
such an apparatus.

When are you going to get your distemper shot? |-O

From _The_Book_Of_Wireless_ by A. Frederick Collins (1915):



\ \ \ Earth Ground

The ### is an ``...interrupter - a device which makes and breaks the battery current several hundred times a minute.'' This is necessary to induce current flow in the secondary. Try using various relays with the battery voltage going through the Normally-Closed contacts. (His version actually used the primary's iron core as an electro-magnet to pull-in a piece of spring steel thus breaking the current to the primary, which then released the spring steel so that contact was once again made, and the cycle repeats. This would give a modulated signal whose audio frequency matched that of the interrupter's freq.

He gives details for a rather complex 1/2 kilowatt transmitter, also.

From the Regulations governing Radio Operators (in force at that time):

Paragraph 122 - Amateur First Grade. The applicant must have a sufficient knowledge of the adjustment and operation of the apparatus which he wishes to operate and of the regulations of the International Convention and Acts of Congress in so far as they relate to interference with other radio communication and impose certain duties on all grades of operators. The applicant must be able to transmit and receive in Continental Morse at a speed sufficient to enable him to recognize the distress calls or the official Keep-Out signals. A speed of at least five words per minute (five letters to the word) must be attained.
...amateur stations shall not use a wave length when transmitting which shall exceed 200 meters; or a transformer having an input exceeding one kilowatt...
...The written examination consists of seven question and to answer these you should know:
1. How to make a diagram of the transmitting and receiving apparatus.
2. How the transmitting apparatus is made and how it works.
3. How the receiving apparatus is made and how it works.
4. The International regulations for wireless communication and the United States wireless laws and regulations.

Hi,
I came across a Teledyne/MEC M5842-A TWT. Based on the WR90 output flange, it looks like it may be usable on 10Ghz. Anybody have any info on it, data sheet, or a contact to the mfr?

Thanks,
Joe - AA3GN

Several places. Richardson Electronics, Penstock, Allied Radio, Newark Electronics, etc.
They all use the same price lists and for small quantities they will all be about the same price.
Ham or electronic Flea markets or surplus dealers are another possibility but may not have what you want and may be more trouble than the money you save.
Unfortunately there are not many manufacturers and thus not much competition, especially in very small quantities.

3709. Need help modifying older handheld for 2M

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-18 00:00:00 UTC
From: Kendel McCarley <kendelm@stat.nursing.arizona.edu>

Source record: 111135

I picked up a box of older, crystal-controlled 150 MHz band FM transceivers that were headed for the trash can after the owner denuded them of antennaes. They will all operate on two channels and have seperate crystals for send and receive. The two models that I have several of seem to have remarkable similar circuitry (same Motorola parts, similar layout, etc.). Yes, they all seem to work for their current frequencies.

Changing the crystals seems rather trivial, but I don't know what I need to do to tune the rest of the radio for two meter use. I don't have any schematics for these radios. Does somebody have any pointers to schematics or (better yet) advice on how to use these on two meters. I've had my license for over a year and, being a poor grad student, would just love to finally get on the air for the cost of a little time.

The radios are: Regency UC102 and Fujitsu Ten Limited FTP15-292L

Thanks,

I agree with Gary. But with practice it works ok.
I have also use standard transparency with pretty good results.
But it takes even more practice to use it.
Also the standard film heat tolerance is a lot closer.
You have to have iron at just the right temprature.
But it beats using film on smaller projects.

Umm, Jeff, maybe you ought to have a look at 47 CFR Part 15 regarding
permissible levels of unintended radiation before you make a
blanket declaration of the legality of operating a spark gap
transmitter. I'd guess all but the wimpiest SG transmitter
violates some of the limits.

Of course, you can operate anything you want in a Faraday cage...

One interesting reference is _Wireless Telegraphy and Telephony Simply Explained_ by Alfred P. Morgan (Norman W. Henley Publishing Co., 1915). It shows many circuit diagrams - with the components drawn as pictures - for both untuned and tuned spark transmitters, and also *spark telephony transmitters*. Antenna systems are shown in some detail. There are many photographs of the components (crystal and electrolytic detectors, close coupled helixes, complete station and portable (military) equipment...and photos of Jack Irwin and Fesenden. (The description of the operation of the "Audion" - which was used then only as a detector - is of course not entirely correct.)

> (they also have a general electronics,communications catalog).
> --

Motorola makes an ECL part called a universal hexadecimal counter (MC10H136P, $12.54 in single quanity according to a recent Newark catalog). As I understand it, this counter can be used as a programmable divider with the divisor having any desired value between 1 and 256, including 10. This is done by presetting the counter with a (binary equivalent) value of 256-(desired divisor), and then counting the carry output. Each time the counter rolls over, it resets to the preset value, and counts from there to 256. It would be easy to make a switchable divide by 10--divide by 100 counter by switching the preset between 246 and 156. This counter works up to 550 MHz if I remember the spec. correctly.

Good luck!

I am pleased to announce a new product offered by Positive Time Systems called the RCS-I. This is a radio controller that connects to any VHF/UHF transceiver and can issue x-10 commands. (X-10 is a power line standard for controlling devices throughout a building. Sears, Radio Shack, and others offer these compatible units)
The unit also has an alarm input, a listen feature, a short voicmail box, and responds to all commands in a pleasant female voice. The system IDs with your recorded voice and call sign. This description doesn't do the product justice, so please check out the new homepage at :

http://www.halcyon.com/pos.time.sys/top

or you may email us with you address so that we can promptly send you our brochure and newsletter.

NOTE: This product is intended for US voltages of 120 / 220 VAC. Another version is offered to support other international power standards.

FLASH! NEW FEATURE! The RCS-I has a new feature called Secure Access Mode(SAM). When enabled, the access code changes dozens of times per hour, making it virtually impossible to hack into.

Thank You,

Marshall Craw <mcraw@halcyon.com>
Positive Time Systems
North Bend, WA

What do you mean, "is not clear"? Do you mean the frequency response is
not flat across the bandwidth of the filter in use, or do you mean that
the audio is distorted, or do you mean that the signal is weak and noisy,
etc? More information please. Detail the symptoms, and the conditions under
which they appear, and we'll try to help.

From: Gary Davis <gdavis@gladstone.uoregon.edu>
Subject: Divide by ten front end for frequency counter

My frequency counter tops out at 30Mhz. I would like to build a
divide by ten front end to increase the range to 300Mhz. Can anyone
refer me to a schematic that would serve this purpose? Any and all replies
will be most appreciated.

Regards,
Gary Davis

Subject: Divide by ten front end for frequency counter

ARRL 1991 handbook has a nice counter front-end, with a MMIC amplifier before
the divider. I'm using this, except I use two MAV-3 amps, as they were to hand.
I get about 10-20 mV rms upto 550 MHz.

> (they also have a general electronics,communications catalog).
> --

Motorola makes an ECL part called a universal hexadecimal counter
(MC10H136P, $12.54 in single quanity according to a recent Newark
catalog). As I understand it, this counter can be used as a programmable
divider with the divisor having any desired value between 1 and 256,
including 10. This is done by presetting the counter with a (binary
equivalent) value of 256-(desired divisor), and then counting the carry

output. Each time the counter rolls over, it resets to the preset value,
and counts from there to 256. It would be easy to make a switchable divide
by 10--divide by 100 counter by switching the preset between 246 and 156.
This counter works up to 550 MHz if I remember the spec. correctly.

Good luck!

Jon

How about winding on the threads of a bolt or machine screw? It works
great. Thanks to Ten-Tec for this tip, from their 6-meter transverter
kit instructions.

Subject: Inductor coil

Hey...I'm building this Radio and I chipped about 20% off of the
inductor coil that screws into this metal silver box. The RF signal quality
is pretty bad, and I'm associating it with the chipped coil. I've reordered
a new one, but it seems odd to me that it still works with the chipped coil.
should there be much improvement with the whole coil intact? I don't really

know much about how this thing works (all I know is that it tunes the freq.)
and I don't know what quality signal to expect. If someone could explain
this inductor coil for me...
thanks

Subject: Modulating VCO's

Well -
I may be horribly wrong on this, but why not use an Armstrong FM modulator ?
I have a very fuzzy remembering of this type of modulator, but I faintly
remember that it involves a phase shifter and no PLL, other than the one
needed to generate the unmodulated carrier.
With this scheme, you avoid completly the lock up time.

Without any type of warranty !

Any kind of phase modulation (versus frequency modulation) is
going to have inherent pre-emphasis and very poor low frequency
response. For sending baseband data (such as 9600 baud GMSK),
these are both disadvantages. For sending voice or audio
modulated data (such as 1200 baud Bell 202), this is fine.

We got a laser printer for home use a year or two ago. I got "demo"
pages from several brands at the local computer stores, took them home,
and tried ironing them to a PC board.

There was a wide variation in how well the toner sticks. The cheaper
Brother laserprinter was best.

>found on a hf receiver board? Any ifno appreciated.

You can unsolder it and connect it to a signal generator and excite
it at 10 MHz. A regular diode (assuming it's not a power rectifier
type) should have little trouble recovering in the 50 nSec. available.
A PIN diode will have a very long recovery time and be unable to
rectify the 10 MHz. Compare to a known reference like a 1N4148
switching diode.

Subject: Trouble with MRF141G - 300 watt amp

I am having trouble with an amplifier I have built per motorola application
note AR313. The trouble is the MOSFET conducts (drain to source) when no gate

voltage is applied. This is not supposed to happen. This happens regardless of the configuration the gate is in. By this I mean the gate is not supposed to float or be left open at any time. I ground the gate and the devive still conducts! I have checked and rechecked the circuit and all components two dozen times. I have compleletly disassembled the amp and put it back together a piece at a time testing the circuit at each step of the process. It still conducts. The device is not completely turned on as it draws about 700ma. Several other strange things are occuring. When I turn the power off my amp meter still shows the device drawing about 5ma? Stranger yet is that this 5ma draw seems to change with respect to the amount of sunlight hitting the device? When shaded the current draw drops to around 2ma. This is a very simple design and should be easy to build. I have had nothing but trouble. The only thing I can think of is that I am going about testing and setting the idle current all wrong. Does the device need to have input and output loading on it when setting idle current? Or in any testing? Any help would be greatly appreciated.

Years ago, when I had one of those Radio Shack 100-in-1-run-wires-to-springs electronics kits, one of the projects they had was a "spark gap generator", which they said you could test by "looking for interference on your TV" whenever you turned it on.

Try one of those.

I just got my tech class ticket and am starting to put my
shack together. I don't have much radio gear (yet ;-)
but I do have a lot of electronics gear.

I have OScopes at 35MHz, 50MHz and 75MHz. I would love to put
these to use in my shack. Can someone point me at articles
that would help me in getting the most out of these for use in
HAM activity (I'm a digital guy, I've only used them for
monitoring trigger conditions, etc.)?

I would specifically like to put off purchasing a VSWR meter
for a little while (until my the cost of a new HT wears off :-)

Advice in mail or news is also appreciated!

3727. An image rejection filter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-18 00:00:00 UTC
From: elendir@enst.fr
Message-ID: <4131ub$d5n@cismsun.univ-lyon1.fr>
Source record: 111271

Hi again and again.

Having recently stumbled upon a 26,730 MHz XTAL, I have planned to build a simpleCB canal 19 RX (26,730 + 455 kHz = 27,185) - that's very handy over here for traffic infos.
Anyhow, I must build an input filter that allows 27,185 to pass freely while attenuating the image at 26,275 by at least 40 dB. I don't want a 9th order elliptic filter, obviously it's a fancy to build. What can I do (except buying a 27,185 XTAL ?)

Thx es 73 de ...

>>Try building a half wave rectifier with it. A PIN diode won't
>>rectify very well.

>>N6RK

Add to that....at higher frequencies. They work fine at low frequencies and depending on doping they have about the same forward drop as a conventional rectifier at dc.

The best way to tell is to look up the number in a listing or contact the manufacturer. Any test would have to be exhaustive and involve testing at the operating frequency range of the diodes. Some PIN diodes work as PIN's at fairly low frequencies (like 1.8 or 3.5 MHz), but most do not behave like PIN diodes until mid HF, upper HF, or VHF is reached. The voltage drop is no way to tell, and neither is LF or any dc parameters.

Given that all three of my remaining motorcycles have resistor spark plugs (which lengthen the time the spark takes place and significantly reduces the RFI issue) and happen to contain the spark gaps inside very small chambers (especially small on the YSR50), they don't create much interference. I suspect they'll do just fine from a Part 15 perspective.

>My `blanket declaration' mentioned low wattage with no aerial. A

>
>Greg KO6TH

TCM3105's are still made, probably solely for the ham market. Newark, JDR, and Jameco would be good US places to check, as well as any full-line TI distributor. I don't think anyone other than Texas Instruments made them.

I didn't look at the schematic, make sure there is a provision for adjusting the bias level on Pin 7 as this is critical for good reception. Sometimes the design is cheapened by using 2 fixed resistors rather than a pot there and this may not work well with some 3105's.

As for software, download Baycom 1.5 from your choice of a large number of ftp archives. This is good entry-level end-user AX.25 terminal software. Various other software drivers for other applications are also available. The Baycom group also maintains a Web page at http://www.baycom.de.

I've had _very_ good results using Techniks' Press-n-Peel Blue sheets. Some experimentation is required to find the appropriate ironing temperature, and you must allow the board to cool completely before removing the sheet. I've made many single and double sided prototypes this way with great results! I'm using a laserjet 4P printer, if that makes any difference.

Good luck,

Chris

Motorola has a MECL divide by 10 with TTL outputs that's good to 550 MHz; MC12013. In addition, Newark, Hammond, etc. have enhanced 7216 series counter chips that provide period measurement, etc. It should not be too difficult to build a 3 GHz unit using a divide by four, xtal reference, "mar" front end and a handful of support chips.

Help!

The Las Vegas chapter of Tripoli -- the national association of high power rocket enthusiasts -- is preparing to challange the world altitude record for high power rockets -- currently about 37,000 feet. We need help locating plans or a schematic for a tracking transmitter, antenna and receiver for the record attempt. Here's what we need:

The transmitter must be able to fit into a tube that is 1-1/2" in diameter and no longer than 12 inches. It must operate for a minimum of one hour on batteries and be as light as possible. The operating frequency is not important as long as it is in the amateur bands. We need a minimum range of about 15 miles line of sight. The body of the rocket is constructed from phenolic-impregnated Kraft paper overwrapped with fiberglass. An antenna can be glued to the outside of the rocket body -- perhaps copper foil tape or some similar method. Radiation pattern from the transmitter should be omnidirectional, because we have no idea as to the position in which the rocket will land.

The receiver can be just about anything that we can carry, as long as it is battery operated. The receiving antenna should be highly directional and hand held.

If you have any suggestions on how I can obtain or construct a transmitter/receiver combination that will accomplish this task, please e-mail me at

UYFA59A@ Prodigy.Com

If you have any interest in being a part of this, let me know also. The attempt will be made in about 6 months, most likely in the Black Rock Desert of northern Nevada -- about 80 miles NNE of Reno.

Thanks very much for your assistance.

Sounds good. What are the tolerances of garden-variety bolts, with respect
to threads-per-inch and linearity thereof?

3739. VCO noise, again - with a PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-20 00:00:00 UTC
From: elendir@enst.fr
Message-ID: <41725m$h8t@cismsun.univ-lyon1.fr>
Source record: 111148

Hi everybody,
I'm back with that VCO noise problem.

This time, however, I'd like to know how much can a PLL with, let's say a reference of F Hz, reduce a VCO noise under F.
Does anybody have any clue ?
And then, is there a special way to design the loop filter in order to improve the noise figure while keeping all other parameters (lock time, sideband suppression) acceptable ?

Thanks,
Vince

Actually, I DO read the groups quite often. My inflamatory response was directed at ALL of the "gee you sure are stupid for asking that kind of question" responses, not just the poor sole that finally drove me over the edge of inFLAMity :-) So it wasn't personal though I'm sure it seemed that way.

I see a fellow ask a perfectly innocent question, and the first 10 responses imply he needs a new science project. These responses all have the flavor of the parent chiding the uneducated child for being about to stick his finger in the flaming gas burner.

No one seems to make the presumption that the gentleman knows what he is doing, understands the law, and then proceeds to answer his question or at least enter in to an interesting discussion on building spark transmitters.

This kind of behaviour is common here on the newsgroups. But my original statement prevails -- it IS RUDE. And its unnecessary. One could certainly say the same thing about my post -- but, this was the third thread I had read today which consisted of the same kind of responses and I quite simply lost my cool. Which is no excuse, but some explanation.

I personally get tired of reading the stuff -- since it costs me money to access these newsgroups. The net has become overcrowded with folks who seem to take great delight in pointing out the flaws in what someone has said. Fortunately, one occasionally finds something of value amongst the chaff - and there have even been some posts on spark gap references.

Peace ....

Grant/NQ5T

I am not sure why everyone is stuck on the iron-on transfers. I have tried this with limited results. Instead, we just have the circuit board house we work with laminate the positive working film they use to a blank panel. Then in a dark room, I just cut off the size needed for a prototype. Just run your pattern on overhead film for the positive and expose the board with a UV rich light source (sun lamp). Develop in sodium carbonate (one cup per 15 gallons of H2O), rinse and then etch. This is far cheaper than what is charged for the film and produces much better and consistent results. Most areas have circuit board shops that will probably be willing to do this. It seems someone could really do the home shop market a service by just buying a laminator and supplying via mail order panels already to go. We are busy enough but a retired amateur could certainly augment his or her income in this manner.

Indeed, you DO deserve a reply. When a small tad (am now 67, I think....), I built my first spark gap transmitter using a Ford Model T spark coil with "plans", if you can call them than, from the Encyclopedia Britannica Jr.

It certainly put out a signal around OUR house and the neighbors, too. Got me interested in radio.

There should be any number of historical referrences that would contain instructions on how to build one - you've been instructed by others concerning the legality issues and I need not comment on them. Rotary spark gaps provided a higher "purity" signal than fixed gaps.

There shold be a wealth of info in rec.antiques.radio+phono. Followers of that group will provide you with any info you require, I'm sure.

: Agreed. Just don't feature it as a construction article which was clearly
: done (see the cover.)
:

It depends what you want from the project. If you want an excellent keyer at a much lower price than a fully-assembled unit, it's a bargain. People who buy for this reason won't be interested in the internal coding, any more than they'd be interested in how a fully-assembled commercial unit works internally.

ARRL promoted the keyer in the above way, but also as a simple, reliable project for the beginning constructor. You might call it nothing more than "assembly", but for a raw beginner the techniques of stuffing a PC board, deciding where to locate the major components and drilling the necessary holes in the box are all something that's got to be learned. With very little help, a complete beginner can end up with the satisfaction of having built a top-class keyer (and that will incidentally help to develop an active interest in CW - a clever bit of promotion on ARRL's part.) As with the "users", this group will have relatively little interest in the detailed coding - their interest is primarily in a construction project.

The third group are the computer techies who are interested in how it's done. This is the only group that might protest about the lack of information. (It's also worth noting that this group may be over-represented here on the Internet, relative to the amateur population as a whole.)

Several thousand people have bought the kit and been delighted with it. Before buying one myself, I asked here and directly to US hams, and the response was unanimously enthusiastic. The keyer is just one example of a whole class of projects which use quite complex digital technology to do something very practical and easy-to-use. The vast

majority of users will be very happy to leave it at that, and grateful to whoever did the digital wizardry.

The particular feature of this keyer is that it was developed with strong input from world-class CW operators, DXers and contesters. Some quite subtle thought has gone into the provision of the needed features in a way that's easy to use - but I don't imagine that the coding itself is particularly subtle.

Remember that this keyer was NOT promoted as teaching anybody anything about programming. It was promoted directly to the users and constructors, and for them it has been a resounding success. If the article had been presented as a programming tutorial project, it would have been far higher-level than the actual article was. If you really want to know how the CMOS Super-Keyer is coded, read the specification and functional description in the manual that comes with the kit, and write a 'clean room' clone of your own.

I agree with Gary, that the people who developed the program are entitled to hang on to the source code. If you add up all the costs of purchasing the components, burning the chip, assembling the kit, printing the manual and handling the administration and mailing - not to mention the untold hours of development time - they're not making much profit out of your $45. By setting the security bit they are also protecting themselves against hassles due to other people selling rip-off copies and circulating well-meaning "improvements" that actually aren't.

Here's my challenge: is there anyone in this newsgroup who has actually *bought* the keyer and still begrudges the money?

There are also the practicalities of magazine publishing to consider. Every article has to compete for space with other articles, on grounds of interest and relevance. As a professional author and editor myself, I would have accepted the Super Keyer exactly as QST did, as a constructional article. If the same authors had also submitted a long and detailed article on how it was coded - and it *would* have been very long and detailed - as an editor I'd have thought very hard before accepting it, because it's only the end-product that is directly connected to amateur radio. Most of the techniques described would be equally applicable to programming the proverbial toaster, I'd probably have suggested the authors rewrite the article for a general-interest digital electronics magazine.

Some people may interpret the Super Keyer as a "dumbing down" of QST and amateur radio in general. Personally I think the editors are right to try and keep the focus of the magazine on *radio* techiques, and to devote all the page-space they can to that.

3753. Re: VCO noise, again - with a PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-21 00:00:00 UTC
From: Eliot Fenton <72633.3247@compuserve.com>
Message-ID: <41a4f2$ue1@bud.shadow.net>
Source record: 111073

Vince.....
I came into your discussion late, however it appears you are asking about phase noise with regards to VCO's and loop filters. In a nutshell:

Phase noise is related to reference noise, vco noise, divider noise, VCC noise, etc.. The output noise of the VCO within the 3 db bandwidth of the loop filter is approximately (and I use that term "very loosely) equal to 20logN times the phase noise of the reference oscillator, where N is the division ratio. For example, if your reference oscillator is 1 MHz with a phase noise of -150 dBc at 10 KHz, and your 300 MHz VCO is phase locked to it, then your 300 MHz phase noise at 10 KHz offset would be 20log(300MHz/1MHz) + (-150 dBc) = -100.5 dBc. Essentially, the phase noise of the reference is "multiplied up" by the division ratio.

The Phase noise limit for CMOS dividers is approx. -150 dBc; for ECL approx. -130 dbc. This should give you an idea of the ultimate phase noise floor you will achieve with various components.

As far as your question regarding sideband suppression and noise, these are all tradeoffs which the designer has to contend with. When designing low noise units, it's customary to use different phase detectors for different applications. A sample and hold is good for low noise, but not for acquisition or switching speed. Conversely, the tri-state detector is good for speed and acquistion, but only mediocre as far as noise is concerned.

Obviously, there is a great deal of information that you will have to digest to understand the subject completely, certainly much more than I can explain here. I suggest starting with a book by Floyd Gardner, PLL techniques (I think that's the name, but don't quote me) which is a classic in the industry. Keep me posted on your progress.

Incidentally, my company specializes in VCO and synthesizer design, so if you run into any problems, one of our engineers is sure to have an answer, or at the very least steer you in the right direction.

Best Regards,

Eliot Fenton

It would be much simpler to build one using the 27.185 crystal and use
the 26.730 for receive. You can cannibalize an old broadcast band receiver
for the 455kHz IF. Be careful if you bring it to the US, homebrew CB is
illegal here.

Well, I don't intend to use it as an emitter, just for RX. So I guess
that even American law does not prhibit channel 19 receivers !
Ok for buying a 27.185 MHz XTAL. I guess it's the only cheap and
reliable solution.

Source record: 111078

Hi all

Thanks for the help with the PC power supply. I followed the advice of the first responder, who suggested loading the supply to make it work.

I paralleled two 10-ohm, 2-watt resistors and plugged these into the 5-volt rail, and all was well. So if you can use a PC power supply for another project, This makes for a really simple go/no go tester.

Filtering the hash from the supply won't be necessary for my application, but should be trivial. And providing decent shielding for the power supply should be do-able with aluminum window screen.

When/if I have more updates I'll share them. By the way, junked power supplies are an excellent source of muffin fans, and some power supplies have usable high-voltage filter caps suitable for voltage multiplier HV supplies. The trick lies in getting the kitchen can opener to work on the supply case.

>meter, or sell your hand held to buy some decent equipment.

Actually, SWR meters are vastly overrated devices, and not one of the first instruments an amateur should purchase or build. A VOM is the most cost effective instrument an amateur can own, but an oscilloscope is the most genuinely useful and flexible instrument an amateur can own.

You *can* use an oscilloscope to read SWR if you have reason to care what SWR some transmission line may exhibit (but frankly you usually don't have reason to care). All you need to build is a simple bridge to separate the forward and reverse currents, display the voltages across the respective bridge legs using RF probes on two channels of the oscilloscope, and find their relative amplitudes by inverting one channel and summing, then adjust the gain of one preamp to null the trace. The difference in gain settings of the two channels is then the ratio of forward to reflected currents, or the reflection coefficient. That's usually sufficient, but if you want SWR from that, just crank it through the formula relating reflection coefficient to SWR.

But if you are adjusting an antenna, a relative field strength indicator will be a much more useful device than a SWR meter, and an RLC bridge will be much more useful for measuring the degree, both resistive and reactive, of mismatch in any system. You can use an oscilloscope as the readout for either of those simple devices.

An oscilloscope is valuable because it shows phase effects in the time domain that meter movements do not show. And it is valuable because it shows transient behaviors that meters also do not show. It is easy to spot distortion in signals with an oscilloscope, very hard with just a meter. To learn what you can do with an oscilloscope, a good starting place is the book _101 Ways To Use The Oscilloscope_ published by SAMS.

I find both oscilloscopes _and_ CD players to be most useful for measuring SWR.

Here's how:

CD Player:
Put some good loud music in the CD player.
Headphones over your ears.
Tune out the lab gossip and tune into your task.

Oscilloscope:
Drive the antenna at very low power with a sweep generator,
Thru a forward directional coupler and a reverse directional coupler.
Each coupler to a channel on the scope.
Subtract the forward channel from the reverse channel.
Trigger on start of sweep.
Enjoy your SWR plot to the sound of good music. :-)

Much closer than you're likely to need, or could maintain after removing
the bolt. If the application is really critical, try using using a
threaded former made on a screw-cutting lathe. Wind the wire on tightly
and secure it with coil dope.

For those who are interested, I have used ordinary photocopy paper, and transfered the image onto the PCB using the usual hot iron trick.

To remove the paper, soak the board and paper in a strong (50%) blend of household bleach and water. After a few minutes, the paper will dissolve leaving the toner behind. By carefully using your finger, you can remove the fur left behind.

The new Macintosh Ham Test Simulators are HERE!

Novice Ham Test 5.0 SA.sea
Technician Ham Test 5.0 SA.sea
General Ham Test 5.0 SA.sea
Advanced Ham Test 5.0 SA.sea
Extra Ham Test 5.0 SA.sea

The latest versions feature:

HyperCard 2.3 as a stand-alone application (SA) eliminating the need to have HyperCard. All you need is a Mac with 4 Meg of memory and version System 7 or greater.

Each version 5 Ham Test Simulator has the latest questions as prepared by the Question Pool Committee.

Each Ham Test Simulator is FREE OF CHARGE and work the same way as the originals written by Diana, KC1SP.

You may obtain a Ham Test Simulator by mailing me a *FORMATTED disk (1 per test) and include a Self Addressed and Stamped disk mailer for the return.

Each Ham Test Simulator is also bundled with a shareware CW program called MacMorse 1.4 written by Doug, WB0EON.

Also included are a collection of text files that relate an interesting variety of ideas about the best way to study CW and prepare for tests.

or warm your phone line and get just the tests:

America On Line - Macintosh Ham Radio Section

ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/AdvancedHamTest1.sea.bin
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/ExtraHamTest.sea.bin
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/GeneralHamTest.sea.bin
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/NoviceHamTest.sea.bin
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/TechnicianHamTest.sea.bin

Your comments and suggestions for future versions are always welcome. Stay in touch and good luck with your next test!

Kendel,

changing the crystals might be trivial, but nowdays you might find
it difficult to obtain the needed crystals at a price substantially
less than a s/h 2m HT. If you can find the frequencies of the crystals
employed you may be able to work out the frequency for your desired
channels. the rest is fairly easy, even without schematics: Locate
the TX and RX multiplier chains, tweak them up with a diode RF probe
(You may have to check if you are on the right overtone)
tweak the RX input and PA, and off you go.

>motherboard I can use, but I consider it overkill.

Sorry - the power good line is an output - not an input. It tells the
motherboard that the power has failed about 1/20 of a second before
power to the motherboar dactually dies (i.e. the filter caps in the
supply discharge. Programs that can use it (neither DOS nor windows can)
save info to the hard disk before the caps die.

Sorry.

PC supplies are switchers. they need a load before they work right.
Each output needs at least a 10% load. The fans are generally powered
by the +12 output, and consume about 50-100 ma.

The worst piece of new 1/4"-20 threaded rod I've ever run across was off by about half a thread over a length of one foot. That would be 1/40th of an inch out of 12 inches, or about 1 part in 500. At the time I did the measurement, I thought this was pretty good for ordinary hardware-store threaded rod; I would expect bolts to be much more precise.

In my experience with winding coils, 1 part in 500 in the spacing is *not* something to worry about! When you remove the coil from the bolt, the spacing is likely to change much more than this.

The diameter of a bolt (or the depth of the threads) is likely to vary much more than the thread spacing, but still probably wouldn't be all that important compared to the distortion that will happen after the bolt is removed.

The tolarances are very high for threads. Much higher than any thing that
could effect a coil as much as other components in the coils field.

Good luck

>in the shack?
> All info. is welcome!
> Thanks, Henry (Ke4wbw)
Henry, if you are seriously into frequency calibration of counters etc, there is yet another trick, not so far mentioned, which I claim to be significantly better than most conventional cheap methods.

Here in VK we also have a time/frequency standard VNG on 5.000 MHz. An ordinary direct conversion receiver using the conventional NE602-741-386 line-up will do fine. Do not use the internal LO of the '602 chip, but rather, build a separate 5.000 MHz CRYSTAL controlled VXO LO in an RF tight box. Install a buffer into the LO box, and bring your 5.000 MHz LO signal out on a coax connector in addition to supplying the '602 (ac coupled) at pin 6. Use larger coupling capacitors through the audio chain (say 0.47 uF instead of the usual 0.1 uF's). At the output pin 5 of the '386 (in addition to the usual speaker ckt) install an LED (to conduct) in series with a 1 kohm resistor. When your VXO LO is near zero beat (sub-audible) the LED will flash, or wink. As the crystal is brought right onto frequency, the LED will emit nearly constant intensity, showing that your LO is at true "zero-beat". The 5.000 MHz LO now supplies your shop with a local secondary frequency standard- even if the sation fades out.

Kind Regards,

Drew Diamond, VK3XU

Is the 826 a mercury rectifier?

If so, there's a solid state plug-in replacement available. Alternatively, you can use a hi-volt recitfier module (try Silicon Alley) but be advised that the mercury rectifier tubes caused a significant voltage drop, so B+ may be too high with either "fix."

You may be able to resurrect the nonfunctional 826 by letting it sit right-side up in the chassis for a day, and then slowly bringing up the filament voltage with a variac. Be sure not to apply HV. Give it a couple hours to warm up, then bring the HV up on a second variac. YMMV, but sometimes it works.

Since the 1940s we've forgotten how to care for mercury rectifier tubes.

We've also mostly forgotten (or never experienced) the joy of sitting in a darkened ham shack with the lid off the power supply, using a big plate-modulated AM rig and watching the rectifiers and the PA plates flash and flicker. It's nearly as ggod as the Northern Lights.

>techiques, and to devote all the page-space they can to that.

Nope, the "dumbing down" is in the fact that all the real technical articles from the ARRL are now published in an amazingly thin magazine called "QEX". The fact that it's so thin seems to indicate that it wouldn't be that much trouble to just put them in QST like they used to. Example: In the mid 80s, W7ZOI et al had a bunch of articles published in QST on building your own crystal IF filters using simple techniques and equipment. The only place to find such now is QEX, in fact a couple of articles on that very subject have appeared in there over the last year or so.

BTW, re: the keyer article... even if the editors kept the source code out of the magazine, it would still be nice to see a net address or a mail-order source of a floppy, for those that are interested in fooling around with it. Assuming the authors released it, that is. As far as page space, well over half of QST is ads and junk lists of who got their DXCC certificates, etc... I'd gladly pay an extra dollar a month (QEX is $12/yr for ARRL members) to see less junk and more content.

> When the man says "I know it's illegal but... I want to do it anyway", what does it say
to you?

Apparently *not* what it says to you. Are you suggesting that because some technology is *illegal* to use that everyone should be ignorant of its operation? Several people in this thread, despite the original poster's polite inquiry, have gone ballistic. In 20 or so messages, I have seen only ONE intelligent response, and that was from an individual who pointed out that while the spark might be broadband in nature, the transmitter neednt be.

In the big scheme of things, a guy next door dinking with his spark gap xmitter (and messing up my tv reception) is less offensive to me than the idiot who can legally drive his car down the street, bouncing up and down from the 500 watt subwoofer and the rap CD.

I think underlining the fact that sparkies are dirty (and therefore, illegal) is warranted. Bitching at the guy for being curious is not. I agree with another poster: Lighten up.

3785. 20M/40M mobile antenna problem/question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-22 00:00:00 UTC
From: Jeff Krul <jkrul@equist.com>
Message-ID: <41d6pj$t15@noc.tor.hookup.net>
Source record: 111094

I have a 20M/40Meter mobile vertical which was GIVEN to me by the owner of the HF rig I purchased. (450sat). I constructed a 'mobile' stand for the antenna out of plywood for DX expeditions away from home. The base of the mobile antenna sits about 10feet off the ground when on the stand.

I am having a problem both rx and tx. When receiving, all signals seem 'low' and the noise floor is pratically GONE. When transmitting, I have no problem tuning the antenna with the 450sat, but good luck trying to make contact!!! I was lucky enough to make contact ONCE from Toronto to Vancouver Island. His signal was <3 s-units and my report was not mentionable.

I have no ground to speak of since it is mobile. Do I require a ground plane immediately under the antenna, such as 4 horizontal radials, or on the ground with lots of wires?

I never had a problem at home with the R7 since it is relatively ground independant.

I would appreciate any information e-mailed to: jkrul@equist.com.

I wish I had the name of the company off hand, but one of the toner transfer PCB products I've used, touted their product for producing panel graphics as well. In brief, you print on their release paper, spray the printed side of the paper with clear lacquer and let dry. Then, cut the area out you want to use as a transfer, soak in water for a few minutes and it slips off the release paper just like a decal (for those that have built styrene models). They say it should work on other types of printers too (probably won't work on inkjets that use water soluble inks, IMO).

Hope this helps.

[stuff deleted in the interest of brevity]

Hear Hear!

ARRL touts QST as benefit of ARRL membership and not a magazine subscription. This used to
be
true; except for a few ham radio stores, the only way to get QST was to join ARRL. Now it's
available at any good bookstore. ARRL has changed its focus from a service to its
membership
to a publishing house that markets its products to the widest possible audience. To appeal
to
this greater audience, it has "dumbed down" QST and increased its revenue base by
publishing
an expanding array of specialty publications such as QEX and the Antenna Compendia. If you
want the good stuff (and I do) you purchase these too (and I do that too). Now I spend at
least twice as much per year to get the same stuff.

If you think this is harsh, check out the August issue of QST. Nineteen pages have ads for
ARRL stuff. If I counted correctly, 14 of them are full page. That's 7% of the rag taken up
with self promo material. No wonder there's no room for techie stuff.

How do you make the divide by four that operates to 3 GHz? I was under
the impression that some sort of frequency conversion scheme was used to
bring high frequencies down prior to the dividers and counters, but direct
division would certainly be a lot easier.

Cheers,

Jon

Jeff,

you simply observe what is bound to happen. If you want to go
portable, not even to mention a DXpedition, you want the best
antenna you can manage. So sell the dummy load and use one of the
following:

Horizontal dipole or loop, at least 1/4 wl up for inland, if
ground conductivity is low.

quarter wave vertical near the sea if ground conduction is good.
Make sure to provide a good ground plane for it, e.g. 60+ radials
on the ground of 3-4 radials 1/4 wl up.

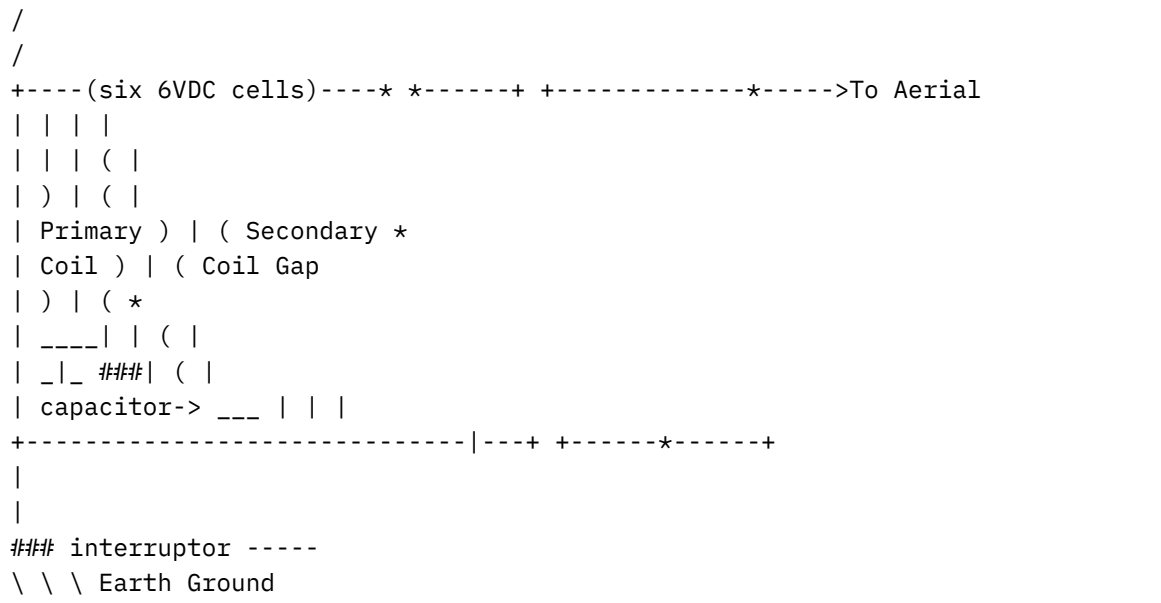
Nice posting on this tx, thought I'd add my 2 Belgian cents worth.



Try putting a capacitor - needs a high voltage rating, say 1-2000V, across the interruptor contacts. The object of this is to reduce arcing at the contacts and thus reduce wear, I recall that the big (6 inch diameter and 12 inch long, making 5-6 inch sparks!) induction coils we had in the school physics labs had their interruptor contacts protected in just this way. The capacitance is not critical - 1uF will do, but it needs to be a non-polarised i.e. paper or oil type, as the voltage produced by the collapsing field in the primary when the circuit is broken will be HIGH ! Depending on the primary inductance and the number of cells you use, you may even need a higher voltage rating, as this cap will be under some stress ! Motor start capacitors could be ideal for this as they are designed to operate under harsh conditions with an inductive load. Incidentally, not only will the capacitor reduce contact wear, but as the arcing at the primary is reduced, so will any interference be which it might otherwise have caused. It's the spark gap at the secondary which is meant to generate the RF !!

Without this protection, I suspect relay contact life will be short, but then again, for a science project this may not matter.

Good luck !

Filtering might be very difficult in a reasonable space. There is such thing as an 'image-reject-mixer', that dont respond to the image. However, fitting one would not be trivual. Look in an RF book for circuit. I cant recall it.

I need to make a double layer board. I've done it before with rather cheesy connections between the layers, but need to do a better job this time or I won't be able to get to my solder connections.

Anyhow, I've looked at tining kits, but still don't have a clue as to how I make a thru plated hole.

Anybody know?

Thanks,

Kendel McCarley kendelm@ece.arizona.edu

Amateur TV Quarterly, RF design and 73 magazine both published
articles on this as I remember. The designer was Dave Pacholok. John
WA8EOY also built one. Probably before 1991. Nothing in QST.

Zack
zlau@arrl.org.

I've now worked 9 states from Western Mass on 10 GHz.
Anyone in DE or MD for skeds?

3804. Drake R7 VCO hosed: stuck at 51.950 MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-23 00:00:00 UTC
From: russ
Message-ID: <41e6pq$8ir@ddi2.digital.net>
Source record: 111113

I have an R7 with the digital readout installed that worked and then froze on the above frequency on the display. I think I've narrowed it down to the VCO board, probably the MC14046 PLL or one the the following UA739 opamps stuck on the positive rail, which might account for the failure mode.

I'm going for the CMOS PLL first. If anyone has experienced this, please post! Can't afford the nearly $300 drake wants to fix it. Any other R7 lore would be likewise appreciated. I've got parts of it modeled on the computer with SPICE; I've seen mods for the TR7 in Communications Quarterly (the only receive function being a BCB sensitivity improvement mod) and am looking into R7 mods.

You might try Motorola. I talked to an ex-TRW engineer shortly
after the Motorola acquired parts of TRW. Thats why Motorola has
some parts with numbers that I used to think of as TRW numbers.

Request a catalog from Fair Radio Sales and scrutinize every page for these things. You can get good ceramic switches, multigang even for 3 bucks. If you choose to part out a subassembly from them, you can really score. Marvelous stuff for the home based cannibal!

GEC-Plessey make 3 GHz dividers. I've got their catalogue somewhere if
you want more details.

It can be done. But you would be way ahead of the game if you simply
paid the 2 or 3 hundred dollars necessary to get a commercial outfit
to make a board for you.

No need to pay big bucks for good quality prototype PC boards. Check out AP Circuits in Calgary. There bulliton board is (403) 291-9342. Download NEWUSER.EXE for details on their service. I believe they even have a shareware PCB layout program that you can download and use. They will deliver two 5x6" board in just a few days for only about US$ 79. I belive thay have a website, www.apcircuits.com/htmls/apc/apdel2.html

Greetings, all, from a warm and sunny Diepenbeek in N.E. Belgium !

" The really big VLF transmitters weren't sparks. They were AC generators
that worked at RF frequencies (or with mag amp frequency multipliers).
Or were hydrogen arc transmitters that were negative resistance oscillators
much like a multikilowatt neon lamp. Both of which output CW, as opposed
to the damped wave from a spark transmitter.

I sure wouldn't want to hang around the keying relays when one of those
things was sending.

Mark Zenier mzenier@eskimo.com mzenier@netcom.com "

If I recall correctly, the AC generators went by a name like Amundsen
Alternator, or something similar. They had several hundred pole pieces,
rotated at high rpm and had an output of the order of 20-30kc/s. Two remain
in existence in the world, one in Scandinavia, I think Sweden, which is
occasionally wound up to show visiting statesmen (not hams who might understand
it !) and the other is on the Eastern seabord of the USA somewhere, I think -
and is fully operational, only closed down in the 1960s. There was an issue
of "Morsum Magnificat" a couple of years ago which carried an article on
these old wonders.

Hydrogen arcs I confess ignorance of ! If someone would enlighten me, I'd
like to be less ignorant !

I've never been able to get this cheap for boards I've had made for work
related projects. I'm paying a little over two-hundred dollars in setup
charges alone on a current project (photoplots, etc.) and I have shopped
around.

Anyhow, I'd still like to know how to make thru-plated holes. I can't
justify several hundred dollars for a single, hobby-related board;
especially when I could go out and buy a commercial product for about
that much to do what I'm homebrewing.

They are rather specialised, so you might have problems in the US. The GEC Plessey N. American national sales office phone number is (408) 438-2900. They should be able to give you details of your nearest distributor. Pioneer Standard and Insight stock GPS products, and seem to have offices in most states.

A typical component is the SP8904B that goes up to 7000 MHz! They make slower devices like the 3500 MHz SP8835B. 8-) These are both divide by 4s.

For folk who might have a casual interest in early transmitter (and
receiver) technology, look for issues of "Electronics World + Wireless
World" magazine from the UK. Three articles I found that were interesting:

"Marconi's 200kW Transatlantic Transmitter," Jan. 1994, Pg. 29.
This was a CW SPARK (not alternator) transmitter. There were amplitude
ripples, but apparently not a huge percentage.

"The Spark That Gave Radio to the World," Nov. 1993, Pg. 937. This article
mentions spark transmitters up to 300kW, and possible efficiencies up to
60%.

"Germany's Imperial Wireless System," May 1993. From this article, "Before
the evolution of high power transmitter valves, there were three ways to
generate high power CW: Poulsen's quenched arc, Marconi's timed spark, and
radio frequency alternators."

From: Super-User <root>
Message-ID: <41ikb0$qgq@news.duke.edu>
Source record: 110980

I am trying to plot noise figure circles for a preamplifier at 400 MHz. Anybody know a good way to do that?

or:

If I have a 50 ohm source and I want to continuously transform it from some low impedance (around 2-5 ohms) to something like 100 or 1000 ohms how can I do that? This is for plotting circles of constant noise figure on the resistance axis of the Smith Chart.

I am thinking about coupling the 50 ohm noise source into a big resonator and then using a variable output coupling to get my impedance transform. Will that work?

This message isn't truly related to homebrewing but I thought you guys might have the best idea as to what I should try here.

I have been trying to get into RTTY lately but am having a heck of a time with my computer locking up when using 20 or 40 meters. It's ok on 10 and 15. I have the cpu unit grounded have coils on the cables going into the CPU but it really hasn't even made a differance. Any help on what to try next would be greatly appreciated.

Thanks, KA0JZX

3823. An answer to "thru-plated holes"

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-24 00:00:00 UTC
From: Kendel McCarley <kendelm@stat.nursing.arizona.edu>
Message-ID: <Pine.SUN.3.90.950824154643.29467B-100000@stat.nursing.arizona.edu>
Source record: 110984

The web URL suggested earlier led me to a seperate site for circuit board fabrication information. The site is run by a company dedicated to getting board fabricators to using non-toxic chemicals.

This site has info on using a special ink to coat the inside of drilled holes so that they can be plated using a normal Cu plating process. To do this, the ink is smeared into the holes using a squeagee, and the excess is then either sucked or blown out. After the board is cured in an oven at 100 degrees C for thirty minutes, it is then "electroplating receptive". This process can also be used for blind vias in multi-layer boards.

Anyhow, the URL is http://www.databahn.net/greenckt/ There is information on all different aspects of producing PCB boards, including "kitchen" multi-layer boards. Also included in their instructions are the neccessary safety requirements (good!). The site is partially finished and should have lots more info on Monday.

I called the company that sponsor's the site (Think & Tinker 719/481-9011) to find out more about the availability of the ink. They were going to post the formula, but decided not to as there is an intermediate step in its' creation that involves toxics (even though the final result isn't toxic). They do sell the ink. Their current smallest size is 140 grams for $172 (part #CH29-0000-000A). It takes 2 grams per board with 1500 holes and lasts about ten years in the refrigerator. They may decide to sell a smaller 50 gram bottle and that will probably be announced Monday on their web site.

It's going to be the first part of next year before I go any further with this. Hopefully, one of you can try out this process and report how it goes. Just to make things clear, I have no connection with Thing & Tinker, Ltd. other than being an interested, possible customer.

How can I found schemes/plans for a radio ? I wanted to build
one -- a very good one, if possible -- and, in order to do that,
I would need a good/very good radio scheme !

Thanks.

Super-User (root) wrote:
: I am trying to plot noise figure circles for a preamplifier at 400 MHz. Anybody
: know a good way to do that?
: steve

STeve :
in order to do that, you would want to have three parameters at 400 MHz :
NF, the minimal noise factor.
Rn : the equivalent noise resistance.
Ys : the optimal source admittance

Your noise factor for a given admittance Y is then :

nf = NF + Rn |Y - Ys|^22 / Re (Y)

Or the circles for a given nf are centered on

Ci = GammaS / (1 + Ni)

Radius : Ri = sqrt (Ni^2 + Ni * (1 - |GammaS|^2))/(1 + Ni)

with

Ni = (nf - NF) * | 1 + GammaS|^2 / (4 * Rn)

GammaS would be the reflection coefficient corresponding to Ys,

Hope this might help

I believe one technique of doing this is referred to as "bifilar
winding" and had to do with increasing the cross-sectional area of the
coil by winding, simultaneously, two wires, which needn't be of the same
diameter, one would suppose. I did just this, when I needed to wrap some
wire around a tubular structure that was too tight a bend for a larger
cross-section wire. You might try something like this, just making sure
that the spacer-wire doesn't contact the wire that's carrying the current...

I am pleased to announce a new product offered by Positive Time Systems called the RCS-I. This is a radio controller that connects to any VHF/UHF transceiver and can issue x-10 commands. (X-10 is a power line standard for controlling devices throughout a building. Sears, Radio Shack, and others offer these compatible units)
The unit also has an alarm input, a listen feature, a short voicmail box, and responds to all commands in a pleasant female voice. The system IDs with your recorded voice and call sign. This description doesn't do the product justice, so please check out the new homepage at :

http://www.halcyon.com/pos.time.sys/top

or you may email us with you address so that we can promptly send you our brochure and newsletter.

NOTE: This product is intended for US voltages of 120 / 220 VAC. Another version is offered to support other international power standards.

FLASH! NEW FEATURE! The RCS-I has a new feature called Secure Access Mode(SAM). When enabled, the access code changes dozens of times per hour, making it virtually impossible to hack into.

This Product will work on other radio services like GMRS. Marine and Business bands!

Thank You,

Marshall Craw <mcraw@halcyon.com>

Steve:

I believe what you are wanting to do is make the noise source look like a
source impedance which varies over some area of the Smith chart.
You can't plot circles ON the resistance axis tho ;-)

You might try using a double or triple-stub tuner,
but understand that you almost need a network analyzer to
measure looking back into the tuner/noise source to determine
the actual source impedance. Also, the tuner losses directly
subtract from the ENR of the noise source,
so you must determine them as well if you want accurate noise figure numbers.

Jon,

You say you have coils on the cables - I assume you're talking about
the serial cable from the RTTY unit and the audio lines. But what
about the keyboard cable on your computer? My experience has been that
keyboards vary in their susceptability to RF - some are immune to it
and others roll over and die when you crank up the power. If you can
borrow another keyboard to try, do it. You might find the problem
there.

What? Only if he wants to stay on six meters or have a mess off switched padders. The 1000 won't even hit 160. I can't run the numbers but if uses the 3-500Z's at anywhere near rating the 1000 won't even hit 80 without a padder.

Try to contact the manufacturers of amps to buy a cap. Ameritron, Ten-tec, etc.
They buy them in bulk, and replacement parts are usually cheaper than surplus sales. I also have a ton of caps like that if you get stuck.

And right you are. Some of the postings have been a little silly for
a "HOMEBREW" newsgroup.

Kendal, I design RF transistors and so as a rule I HAVE to make
breadboard PCB's *fast* to test new designs. No time for outside
services. I use one of those engraving machines to "etch" the PC
board, but I'm still left with no through holes which makes for very
poor RF grounding. Here are a few things I do:

1. Copper or brass shim. You can get it in real thin sheets (around
003"-.008" thick is best), and sometimes in rolls for bigger jobs.
Cut a thin strip (1/16" works fine) to about a .25" length and feed it
through either a pre-drilled hole, or a slit made through the board
with an exacto knife. I use a small hole for FR-4 (your most common
PCB material), and a slit for the more expensive (and softer)
Teflon-Fiberglass material used in microwave applications. Now bend
the "tabs" sticking out down flat on the board and solder both sides.
They can be bent down in either a "Z" shape, or fold the top tab back
over in the direction of the bottom tab to make a "U" shape. If
you're clever, you can even make a 90 degree bend by folding it as it
comes up through the hole. You can connect traces top and bottom by
using combinations of the above.

2. Brass eyeletts. A little harder to find, but work great. You buy
them according to the thickness of your PCB. They come a little
longer than the board is thick. You put several at a time into
pre-drilled holes, and place the PCB on a hard, flat surface. (At
this point you are supposed to use a special tool, but the following
technique work fine.) Hit the top of the eyelett lightly with a

center punch to flair it out, then flatten it down to the PCB with a small hammer. A little solder top and bottom and you're all set.

3. A REAL inexpensive way is to use solid copper wire as a "plug" for a hole. Drill a hole exactly the same diameter as the wire you are using. Now you can feed a short length through the hole. Place your PCB on a hard surface and trim the wire using good "flush cutting" wire cutters a little bit above the PCB surface. You'll have to experiment with the length. Then hit the top of the wire with a small hammer. It will mushroom out slightly pinning it in the hole. Solder it in place and you're done.

There are easier methods, but one of the criteria I have to use is the bottom surface of my PCB end up as flat as possible to mount it flat on a heat sink. Otherwise you could simply run a wire from top to bottom through a hole and be done with it. Whatever works for your application.

I use the above methods to build prototype RF boards that perform well past 2 GHz. These ideas are NOT mine, I just use them. Good luck with your project! Other helpful comments by hams are encouraged here.

3842. Re: Noise Figure Circles

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-25 00:00:00 UTC
From: jeffa@pax.ssd.loral.com
Message-ID: <1995Aug25.154849.4655@ssd.loral.com>
Source record: 111001

It is not essential to plot noise figure circles for most circuits. As long as the circuit is "nicely behaved" (most amps and low Q circuits, forthat matter, are), you can take measurements at a set of match conditions and use these match points to generate iso-noise match curves (which are usually similar to circles). The same technique applies to load-pull measurements. Of course, you need to know the match that you are providing to the amplifier. This usually means measuring the matching circuit/tuner w/ a vector network analyzer or phase meter. At 400MHZ, you could use a very fast scope to compare amp/phase of the direct and coupled ports of a coupler in-line with your tuner, but then you have to calibrate out the coupler effects (there is loss and phase between direct and coupled ports on a well isolated coupler of, say, broadwall or stripline/microstrip variety).

Another option is to use a tuner or known VSWR match and put a variable delay line between it and a coupler and the amp. As normal, put detectors on the direct and coupled ports of the coupler. Twiddle the delay line through a full cycle of coupler readings. If you can determine a single point on the tuner curve (via phase meter or VNA), you essentially referenced that point to the associated noise figure and all other points since the other points describe a circle locus w/ the Smith chart center as center of the locus. Of course, you still need to measure the noise figure at points along the phase rotation locus of matches. It's just that now, you don't have to determine the match for n arbitrary loads. Even better if you hook a VNA to the coupler and calibrate the measurement system. With this, the match shows up on the VNA and all you have to do is take noise figure measurements at points along the locus.

It all boils down to what equipment you have available.

I think it is an Avantek GaAS FET of some type. We had one of those amplifiers blow out (several stages bad, burned resistors, etc) a few years ago, and sent it back to Mini-Circuits. As they judged it "beyond repair", they they traded it for a new one for about half the price of a new one (still expensive!). I don't know if they still do that or not.

Jeff-

The obvious trouble is that you only put up half of the antenna!
Normally, the vehicle is part of a mobile antenna system, even though it
may be small compared to the wavelength involved. You can't get along
without it, or some equivalent ground plane.

It is also possible to mount a pair of HF mobile antennas on a bracket, to
form a shortened dipole. This won't work as well as a full size antenna,
but is relatively portable. I purchased such a bracket from the company
that sells the "Hamstick" mobile antennas. They had a table set up at one
of the local hamfests. I haven't had a chance to try it yet.

Jon-

Division is easier, but requires longer to measure to the same accuracy.
If you measure to one Hz with a one second time base and divide by 10,
your new measurement will only be to ten Hz.

Some counters, such as the Optoelectronics, use divide by 2 and divide by
4 prescalers for higher frequency measurements. Their circuitry
automatically lengthens the timebase to match, so you end up with the same
resolution at 2 or 4 times the original timebase, without having to do any
math yourself.

How about an air drop? I was always quite fond of black currant myself.
It should stain the building nicely, but you'll need a 45-gallon drum
of it... :-)

But seriously: why would you want to interfere with a LW station? It
is a navigation aid, isn't it? The penalties for doing such a thing
should dissuade you.

But to give an answer: the most effective way to interfere with its
transmissions would be to drive a large truck into the transmitter

Snip ..... Toner is usually a composite of styrene and carbon perhaps with some tint. Normally sepia,cyan, magenta, yellow and black. There are other combinations ..... The styrene is melts or dissolved, applied to the copy(transfer) and fixed by heat, pressure or evaporation.The liquid toners often lack viscosity. In order to create the amount of solid fill necessary to create a decent transfer, you need powder.

The lacquer merely melts a layer of toner off the transfer and causes it to stick to the destination material, When the solvent evaporates, it is set. Try not to smear it.
Good luck

Before I spend money on something that may not be what I need, I'll ask for some advise.

I've got a used R-S DX-440 that seems to be a bit low in sensitivity on almost all the AM bands including all the SW bands. I could test and probably fix whatever's wrong if I could get decent schematics. Is whatever service manual I might be able to get from R-S going to be halfway decent as far as showing me a full schematic with parts values? If so, what's the R-S part number for the manual?

Rogger! Reginald Aubrey Fessenden used the low-frequency alternators. From the book OPERATOR'S WIRELESS TELEGRAPH AND TELEPHONE HAND-BOOK by Victor H. Laughter, 1909 (discussing Fessenden's station - with photos and schematics!):

"The alternator which is used at the present day runs at a frequency of 80,000 to 100,000 per second, and the disagreeable noise at the receiving end has been entirely eliminated. Such an alternator when run at a frequency of 81,700 per second, gives a voltage of 150 volts open circuit and a field current of 5 amperes."

Jon,
You may also want to ground the keyboard with a seperate ground braid. I
opened mine and attached a braid made from the shield off a piece of RG58 to
the ground plane in the keyboard, then ran it back to the PC case and then to
the station ground. I run 1kw on all bands with no problem.

>My next problem is designing a high-input-impedance, high-dynamic-range
>differential RF amp for the output of the phase shift network.

And don't forget low noise, Steve ;-) I work on such ...

>I've noticed the new JPS antenna noise canceling unit (which is a
>phased-array receiving antenna, intended to null locally-generated RFI

I wouldn't quite call it a phased array. You simply either pickup
(radio) or synthesize the offending signal, flip the phase 180
degrees, sum the signals, and voila! Noise reduction. An old dog
learning new tricks...<g>

>noise) must use some kind of wideband phase-shift network, since it covers
>at least 3 to 30 MHz with only a two-position bandswitch: low band and
>high band. Has anyone opened one of these up? What does the phasing
>network look like? Is it a polyphase network? What does JPS use for an
>amplifier?

According to info leaked out, its a hybrid combiner, and accounts for
some loss of the desired receive signal. My guess is that it's
transformer based, the noise signal being fed 180 out from the main
antenna. The phase shift network compensates for phase error due
to parasitics in the network which might cause the noise channel to
deviate from desired 180 degrees as a function of frequency.

I'm guessing here, but WILL find the eventual answer.

I've played with one at a local ham store, and on first trial it did
eradicate some local power line noise. My original desire was for
a wideband antenna phaser for far-field null-steering apps as well
as diversity reception.

Hello,

I have a friend with one of these radios and he would like to
build the interface and program his own computer to control the radio.
The only problem that he has is that he cannot find the protocols that
the radio uses to be controlled. He would like to get the information
that is needed to make the radio listen to the computer commands. He is
most interested in the data bits and the baud rate and what the actual
commands are that need to be sent out the computer serial port.

Please respond via E-mail and here if you have an answer to this.
He realizes that he could do the solution by throwing money at the
problem but he wishes to do it the old fashioned way and do it himself.

A possible approach is to get a TV tuner, the kind that has has a voltage controlled oscillator and covers tha cable channels. I built a sweep generator using one and it covered from 50 MHz to 950 MHz in about 4 ranges each covering approxiamtely a 2 to 1 frequency range. You'll need the wiring information to know where to apply power and how to switch the frequency range. And, then you have to figure out where to couple out some of the rf. That's not too hard since ther is a frequency divider in there for the phase lock circuitry and you can probably steal from its input without messing things up too much. Radio Shack used to have one in a blister pack. And, there have been articles in Ham Magazines about using TV tuners as the local oscillator in a spectrum analyzer. Someone was even selling a kit at one time.

Of course, the grid dip oscillator approach is quick since you don't have to build anything.

>: of "Morsum Magnificat" a couple of years ago which carried an article on
>: these old wonders.

I have been doing some research on these old VLF transmitters in the U.S., and would be interested to know if someone may have more detailed information on this, and others of its type.

In particular I would like to know if anyone knows of archival or book material with pictures of the antenna systems for these stations. I have come across some interesting references to huge systems with antena lengths of nearly one mile and multiple tower with hights of over 600'.

At this time the only station that may fit the discription outlined in the original email would be the Navy station NAA at Annapolis. I've seen it and it is impressive.

There were stations at Newbrunswick, NJ. Rock Point, N.Y. Sayville N.Y., Marion, Mass. Tuckerton, N.J. that operated into the 1960's.

The Newnbrunswick operation was originally a Marconi spark station that was taken over by RCA after WWI.

There was also stations at Arlington V.A., Pear Harbor and Challas Heights (a suburb of San Diego) that had a 100kw, 200kw, and 200kw spark transmitters respectivly.

Any ideas on these ?

There is also a very good book out (who's name I have forgotten) that has a pictorial history of Marconi's huge spark xmitter in England. To give an idea of the scale. First, check out your old ham manuals from the early 1920's and see the diagrams for a spark xmiter. Then upscale it to 100kw. The(as in one)capacitor used was housed in an open two story building. It was composed of metal sheets hung from the ceiling and streached from one wall to the other. There was about 6 feet between each sheet, so a person could walk between them.

The rotary spark was kept in a special containment room, and from the pictures shown, 100kw makes a very impressive show.

I'll look it up if there is interest.

Thanks in advance.

They can get it for you from their service department. Make sure you ask for
THE SERVICE MANUAL, NOT THE OWNER'S MANUAL or else the bonehead will screw up
and send you the wrong one (like they did to me for a DX390).

Your 440 is probably suffering from a weakened or blown 1st RF amp due to
static pickup or nearby lightning strikes, and is typical on shortwave
portables that lack a protective diode network in the antenna input circuit
ahead of the RF amp. You could try tracing the circuit from the whip/ant
jack to find the transistor, and replace it. You might also try asking
on the rec.radio.shortwave newsgroup or the Fidonet shortwave conference,
where this has been discussed in the past.

3884. Need help with VOX/MIC/PTT interface circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-27 00:00:00 UTC
From: stickler@$TIN_DOMAIN
Message-ID: <41qjd2$c8t@news.iag.net>
Source record: 110943

I just bought one of the new Radio Shack VOX headsets, and it works great with my HT, but I also plan to use it with my HF rig. I had no problem hooking up the headphone and mic connections to the HF rig, but the PTT has me stumped.

The HF rig has a stereo jack designed for use with an eletret PTT hand microphone. The base sleeve is common ground for the MIC and PTT circuit, the tip is the PTT connection and the center sleeve is the MIC connection which also provides +8VDC for the eletret microphone element.

The headset has a mono plug. The base sleeve is ground for the MIC and the tip is the MIC input. The headset provides its own power for the VOX circuit and MIC, so the +8VDC from the rig is not needed and I've inserted a capacitor in line to isolate the headset MIC from the rig power.

The problem is that when the VOX activates, the impedance between the headset plug tip and sleeve drops from 4Kohm to 1Kohm -- which my HT is happy with, but the HF rig is not and will not key the transmitter as it doesn't sense a complete short between the PTT connector and ground.

It seems clear that what is needed is a relay circuit that senses the change in impedance and activates a relay that keys the transmitter, but what is the best way to do this?

Any and all suggestions will be greatly appreciated.

Regards,

Patrick Stickler

>
>Hydrogen arcs I confess ignorance of ! If someone would enlighten me, I'd
>like to be less ignorant !

He's probably referring to Poulsen quenched arc transmitters. They used alcohol vapor, which when ionized by the arc broke down to hydrogen, carbon, and oxygen ions. The arc transmitter was a relaxation oscillator, somewhat like the classic NE-2 designs. The plasma has a negative resistance at a certain voltage, pressure, and temperature. Used with a high Q LC tank, a pretty clean CW carrier can be generated. The arc can be "cathode" modulated for AM voice operation (a bank of paralleled carbon microphones was used for higher power transmitters, though magnetic modulators were used too). Some FM is inherent in such a system. It can also be used directly for FM modulation, with a trigger modulator, with better success. (A trigger modulator uses a high voltage, low current, trigger electrode to cause the arc to establish early. Hence the frequency could be shifted up from the natural relaxation frequency by varying the trigger voltage, with a carbon microphone used in a resistive divider, or via a magnetic amplifier.)

Vacuum tubes came late to the scene for high power transmitters because of the problem of making a long life high emission cathode. Hence using ions as the majority carrier retained popularity until the thoriated cathode arrived on the scene and allowed electrons to take over as the majority carrier in high power active devices.

From: "Darius Mostowfi, KE6IL" <darius@megamed.com>
Message-ID: <41qtt9$b9f@noc.usfca.edu>
Source record: 110946

Hi,

I am building a 3'x3' loop for use on 40m - 15m. Does anyone know a good source for a split-stator variable cap, about 5-100pf or so?

Is there anyone out there that can relate any experiences with these types of antennas?

My calculations (from ARRL Antenna Book tables) indicates that a 3'x3' loop at 40m should have -9db efficiency (I think this is compared to a dipole). A 3'x4' loop is about 1 db better. My space constraints may dictate the use of a smaller loop. From what I've read, a small loop should be much more efficient than loading up a piece of wire in an apartment QTH....

Any feedback on these antennas would be greatly appreciated!

73's,

Darius

There was an article in RF Design magazine (rf engineer oriented) and
a follow up (actually a rewrite oriented at ham radio) in 73 several
years ago about turning a microwave radio into a 2gig transmitter.
I remember that they put the modulator in the oven compartment, and
a N connector on the back of the cabinet. IIRC it was 300-600 watts.

From "Sarnoff, an American Success" by Carl Dreher (1977):
"Another factor in the situation was the Alexanderson alternator, a property of General Electric. E. F. W. Alexanderson was a Swedish engineer who, following Fessenden's pioneering, had designed and built a generator on the same general principle as the machines one sees in electric power plants all over the world, mostly dirven by steam tgurbines.....The difference was that instead of producing hundreds of thousands of kilowatts at a frequency of 60 cyles per second, the Alexanderson alternator generated only 200 kilowatts in the largest size, but at a frequency of about 20,000 cycles. This alternator, with its associated equyiopment and a large antenna, would span the oceans reliably."

Hello all:

I have an old GLA-1000 with a new set of NOS 6LQ6's. I really would like to get it to work on 160. I assume it is just a matter of modifying the output network. Has anyone had experience with this? Is there a general procedure for performing 160 mods? I'm willing to "transplant" the amp if there is not enough space in the commercial case.

Also has anyone out there used this amplifier on 20/15/10? If so what kind of output power should I expect for 100w in? I'm asking this because I'm not getting alot and abt 100-150 on 10. I assume this is a limitation of the 6LQ6s.

There are four main areas of concern in a 160M conversion:

1. Input tuned circuit
2. Output tuned circuit
3. Plate choke
4. Filament choke

These issues were pointed out in an article by Rich Measures (AG6K) in "Adding 160-Meter Coverage to HF Amplifiers" in the January 1989 issue of QST. In addition to the above, I think it is a good idea to also verify that the reactance of the plate blocking cap will be sufficiently low on 160M.

Incidentally, in that article, 160M operation was added to a Heath SB-220.

Hi Bill,

I did a little consulting work years ago for Dentron, so I'm trying to
recall the problems you may encounter.

The plate impedance is fairly low, so the choke requirements are not
particulary stringent. A good rule of thumb is the choke Z must at least
equal the plate operating Z, and preferably be greater. Some of the parts
for those amps were bought surplus, so a variety of chokes were used. If
your amp has a solenoid (single uniform layer) winding it may be too
small, if it is a bunch of turns in small scramble wound areas it is
probably ok as is. The old ARRL Handbooks give formulas for calculating
the plate impedance. The newest one is a little strange in some of these
areas.

Some of those amps had tuned inputs. If yours does you will need to modify it. The driving impedance of those tubes as wired in the Dentron was around 125 to 200 ohms. You can start with that and select components from the ARRL Handbooks fopr matching that impedance range to 50 ohms. Dentron raised the driving impedance of the tubes by connecting the cathode to the control grid. This lowered the gain of the amplifier but also decreased the stability at the higher HF region. I thought that was a bad idea.

The tank circuit is incorrect, you can calculate the correct values from the older ARRL Handbooks.

As an additional note, if the gain is as low as you say the tubes are probably shot. A few seconds of mistuned operation at full drive will ruin a sweep tube. The most common failure mode with the tubes is increased VSWR on the input, reduced quiescent current, and reduced output power. With 100 watts of drive you should see a minimum of 400 watts out.

OK, LET ME TELL YOU A STORY... OOPS!
<CapsLock> off... sorry people!...
ahhhhh....that's so much better...
lower case is calming isn't it?

Anyway, the story:

My buddy Bob told me that he once had a neighbour in the apartment
next door with a loud stereo (always "cranked" at all hours, etc).
One day, after many tapes, disks, LPs, etc... he finally caught his
neighbour with the FM tuner "cranked"... (Bob says, "he he he..."
with his best Mad_Scientist accent.)

Signal Generator ON, Modulation ZERO, Frequency 10x.x MHz,
Output Power MAX, ENABLE!... dead silence!... the joys of
the FM capture effect...

My buddy Bob could hear the neighbour muttering "What the 'ell?..."
and walking over to the Killer Sound System From Hell. My friend
Bob heard the hiss increase as the crazy-neighbour turned the volume
all the way to maximum! Bob tapped the trusty signal generator
and could hear the slight oscillator microphonics right through the
cement wall....his finger poised over the DISABLE OUTPUT switch...

"3... 2... 1... <click>."

KA-f*****g BOOOOOOOOOOOOOOMMMMMMMMMMMMMMMMMMMM!

The stereo never worked again...

Darius

Darius et al,

I built the loop antenna described in 73 Magazine May 1995 issue. It is an octagon shape made of 1/2 inch copper pipe and is about 4 feet in diameter. It calls for a split stator variable (found at a hamfest) for 10-20 meters and homebrew capacitors (made of stacked pieces of pc board and place in parallel) for 30 and 40. I haven't used it on 30 and 40 yet. I have a MFJ 20m SSB rig that puts out 12 watts, maybe. I put the antenna vertically on the ground. My first contact (from Texas) was a 59 into Michigan. On field day I set up for about 45 minutes in the backyard and got two Canadians, and a handful of QSO's including North Carolina, Ohio, Nebraska and California. So it works very well. I don't think it would take high power. But with a heavier capacitor or a vacuum variable and beefier construction it would be great.

I'm thinking about making one with a 20-30 foot circumference, 1.5 inch pipe and a vacuum variable for 40, 80 and maybe 160. Any advice on that would be appreciated.

: this, and others of its type.

: At this time the only station that may fit the discription outlined in the
: original email would be the Navy station NAA at Annapolis. I've seen it and it
: is impressive.

I dug out an old book I've got (circa 1928) and it says that NAA was a
500 kW arc transmitter, and the US Navy had a 1,000 kW arc transmitter at
Bourdeaux, France. No more details than that, though.

As far as sending morse with an arc, it seems like there were more ways to
do it than there were parts in the transmitter. Back Shunt keying used a
seperate non raditating tuned circuit and keying switched the arc voltage
between the antenna circuit and the back shunt circuit. Ignition keying
used additional electrodes in the arc chamber to turn the arc on and off.
Compensation keying varied the inductance of the antenna circuit which
caused a frequency shift. And Chopper keying used a motor driven
chopper-commutator in addition to the key to either cause a frequency or
amplitude modulation at an audio rate.

Keeping one of these things operating must have been a chore. Making
sure the gap in the arc chamber was ok, the alcohol drip, the water cooling,
the antenna loading, ... At least the radio room would have been warm.

3909. Neon lamp question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-29 00:00:00 UTC
From: jeffa@ix.netcom.com
Message-ID: <41v2ko$e8u@ixnews3.ix.netcom.com>
Source record: 110968

I recently picked up an old HP voltmeter that uses Nixie tubes for the display (heck, it was cheap). Internally, they use an interesting scheme of coupling the digital data to the nixies (high voltage) by using neon lamps and photoconductors - sort of an early optocoupler design.

The neon lamps used in this optocoupler are supposed to have an "ON" voltage of 55 volts dc. I've found that a couple of digits in the readout "jump" about (from one value to another), and I've traced this instability back to the neon lamps. Several of their "ON" voltages have drifted up to the 70 volt range, which, because of the circuit design, causes instability with a different neon lamp.

My questions are:

1. Do all neon lamps have this same "ON" voltage? If not, are there standard "ON" voltages?

2. Where can I find information on the "ON" voltage? (I've looked in my Allied Electronics catalog, but it was no help).

Thanks,

- Jeff, WA6AHL

3910. Four-bay dipole array

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-29 00:00:00 UTC
From: tkomljan@mobility.COM
Message-ID: <30434BBE@msgate.mobility.com>
Source record: 110969

I have two x Sinclair SRL 210-C2 VHF folded dipole arrays that I would like to phase together to make a C4. Because the mast is not continuous, as in a C4 version, I can't exactly mount the entire antenna above the tower. Rather, the upper two dipoles will extend above the tower for an unrestricted view, while the lower two dipoles will exist on the side of the tower. I'm using TV tower with an 11 inch face.

Question: When a mobile signal radiates from the back (tower) side of the lower two dipoles, the upper two dipoles will get a "better" view. Can the lower two dipoles act as a load (through the homebrew 2-way coaxial power divider) and attenuate the desired mobile signal?

Rephrased: Will this antenna arrangement work without too many undesired nulls?

Regards,

Tony, VE3PEP

Hello Folks,

Digikey is out of the MAX295 filter chip (for the state
variable filter design featured in "QST" recently). They couldn't predict
when they will get more stock. Arrow is out of stock too (and has a
minimum quantity of 50 anyway).
Could somebody point me to an alternative source for this part
that doesn't require a corporate account or large minimum order?
Also, any pointers to a a source for the Maxim databook would be
great. I'm going with the MAX660 charge pump alternative for the -5
supply but don't have the details for this chip. Maxim's phone number
would be greatly appreciated.
I'm also building a Wein bridge type notch filter. I can't decide
whether to arrange for this to be ahead of or behind the state variable
filter when it operates. I can take the empirical approach but wonder if
you wise heads out there know if one ordering would be clearly better than
another?

Hi all;

I am at the very start of the planning of a fox-hunt transmitter system. I would like to be able to put together in an inexspensive way, a transmitter for a fox hunt. The transmitter may or may not be attended. I take it that since the transmitter is acting as a kind of beacon, most likely in say the 2 meter band, unattended operation should be legal. Does anyone know for sure?

I have been considering using an old Icom handy-talkie for the transmitter, does anyone know of any control circuits that could be used to make an ordinary handy-talkie perform as a fox transmitter? I have been considering using a Motorolla 68HC11 microcontroller evaluation board as a fox controller. If anyone has used this or any other microcontroller, I'd like to hear about it.

If anyone knows of a simple two meter transmitter circuit that I could use as an actual transmitter, that would be appreciated. With such a circuit, it would not be necessary to use an actual handy-talkie. Remember that this is just a fox transmitter and will be limited to CW mode on a single frequency. Receiver too?

Thanks in advance;
Jonathan Hill/N1QOL

A few yeas back I visited Acadia National Park on Mount Desert Island in Maine, USA. In the park visitor's center I purchased a small booklet that described a radio station that was operated by the Navy in 1911, on top of Otter Cliffs, which is not too far from Bar Harbor. The station call sign was NBD. I recall from my reading that the station used a quenched spark gap, essentially alcohol was dripped right into the spark gap.....

Oh by the way, Worcester Polytechnic Institute (WPI) became active with a ham radio club in 1909. The club was licensed in 1913 as ``1YK,'' today we are W1YK, so if you come accross either call sign in your literature, thats us. I think that MIT and a small number of other schools also were active at that time, maybe Rensellaer? One story goes that back in those days the electrical engineering department at WPI had a working trolley car. The ham radio club, which was in the same building, connected their transmitter directly to the feedline used by the trolley car. I am not the club historian, so sorry I am not up on all the history. Things at WPI are quite different today than they were back then!

Lastly, I recall hearing about a wireless and steam engine museum in Rhode Island. If I manage to find the brochure, I'll make a posting.

Jeff,

No, they do not all have the same on voltage and yes there are some common voltage lamps. You will have to look at the data from the lamp manufacturer to get the on voltage, measure it, or find someone with the data. My neon lamp catalogs are probably long gone now, but I will look over the next day. Do you know the bulb number (like NE-2 or NE-1-- Etc?)

Use a helical filter from Toko. I have used Toko #271MT-1166A and have great
results with the part. Digi-Key has them (part # TK3601-ND). They can be
retuned a small amount, but be sure you have a sweep generator or network
analyzer, they are very sensitive.

Sony has the CXB1109Q quad ecl flipflop that works until 3.1 GHz typ.
and CXB1104 dual FF until 3.2 GHz.

The Motorola 10EL33 / 100EL33 is a %4 divider that works until 3800 MHz.
It is second sourced by Synergy Semiconductor.

Plessey has, among others the SP4908 2.5 GHz %8 prescaler.

Most satellite receivers have PLL chips with built-in prescalers
that go to 2.6 GHz.

>Does anyone know for sure?

If you classify the transmitter as a "propagation beacon", which seems
to me to be the most correct definition of its purpose, 97.203 says it is
legal to use under automatic control from 144.275 to 144.300 MHz, as long
as the power is less than 100 W, and you aren't in the 'snoop zone' near
Green Bank WV.

> I have been considering using an old Icom handy-talkie for the

>I have been considering using a Motorolla 68HC11 microcontroller
>evaluation board as a fox controller. If anyone has used this or any
>other microcontroller, I'd like to hear about it.

I believe there is a commercial unit to do just that. On the other hand,
it is an excellent introductory microcontroller project. The 68HC11 board
will easily handle the tasks of timing the duration of the transmission,
generating an ID sequence (in CW internally, or use one of those
voice-store chips), and keying the transmitter. The simplest arrangement I
can think of, allowing on-off control and FM-MCW modulation would be:

```
2.2K
PORT --------R1-----*--------------------ICOM Micorphone (Tip)
|
---
--- 0.1 uF
2.2K |
PORT------R2--------*
|
R3 10 ohm
|
GND-----------------*--------------------ICOM Microphone (Ring)
```

Here, the first PORT, when driven low, will pull current thru R1, turning
the transmitter on. (If the microphone jack puts out more than 5V,
additional circuitry will be required). The second PORT, driven with an

audio frequency square wave, allows tones to be transmitted. The ratio of R2 and R3 sets the level and may need to be adjusted.

Another way to do it would be to use a the beacon function of a TNC, this serves the ID and timer functions well, but probably won't transmit long enough to allow anyone to find it. A simple circuit to stretch out the PTT so it transmits a period of dead air after the packet burst may be feasible though.

>
> If anyone knows of a simple two meter transmitter circuit that I could

Building your own transmitter probably isn't justified unless (1) you would like to, or (2) you consider the possibility of an expensive HT being lost or stolen while left unattended high enough to justify it, or of course (3) you don't have an extra HT.

Foxhunting receivers and antennas are another subject altogether.

The larger the circumfrence of your loop, the better it will perform.
The efficiency of small loops (6 ft circumfrence on 20m for example, like
AEA "Isoloop"), is very poor. Expect 8-10 db below a dipole, if the loop
is totally in the clear, and many more db down if in awful locations like
next to buildings or (heaven forbid!) in an attic. A circular loop will become
self-resonant at about 1/3 wavelength in circumfrence.
See latest edition of Kraus's classic book "Antennas" for all the equations
you need to understand small loops.
An octagon loop for 80 CW with 80 ft circumfrence, using 1 inch copper
sweated-joints pipe (about 25 ft diameter, not that large for an 80m antenna),
can have over 90 percent radiating efficiency. Not bad for a small sized
antenna for that band! Not to mention its low-noise receiving and QRM-nulling
capability (easy to mount as rotatable).
The Q of an efficient loop is very high. High enough to attenuate the
sidebands of a SSB signal. This is the reason that efficient loops require
vacuum variable capacitors for tuning. The peak voltage on the capacitor
can (and should)exceed 20KV at kilowatt levels of input power.

> not, are there standard "ON" voltages?

No, they don't. My old Tektronix internal parts catalog shows lamps with firing voltages from 55
to 135 volts. Note that the sustaining voltage is lower by 15-20 volts or so. (This allows them
to operate as a relaxation oscillator, frequently unintentionally.)

> 2. Where can I find information on the "ON" voltage?
> (I've looked in my Allied Electronics catalog, but
> it was no help).

Dunno. I'd imagine that neon bulbs are getting pretty scarce these days.

Maxim are *very* helpful with sample devices. You shouldn't have any
problems getting one of the MAX295s out of them, provided they aren't
out of stock, either.

A PROVEN SOLUTION IS A GRID-DIP METER. I TOO HAVE PUT IT TO GOOD USE IN MY APARTMENT-DWELLING DAYS. MUTES THAT FM SOUND INSTANTLY. BUT, WITH CABLE, IT MAY NOT BE ENUFF SIGNAL TO DO THE JOB. HOWEVER, IF THE CABLE SYSTEM (AND /OR THE TV ITSELF) IS AS LEAKY AS MANY I HAVE SEEN, IT WILL WORK FINE!

3929. EASY CB-to-10M SSB

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-29 00:00:00 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.809739371@eagle.csl.uiuc.edu>
Source record: 111038

CB-band to 10M band....I was pleasantly surprised at how simple it can be.
I was especially interested in SSB for 10M since my son just got his
Tech-Plus license and can operate on 28.300 MHz to 28.500 MHz SSB (apparently
AM is illegal). His "wife's budget" only permitted something "cheap".
I bought a couple of "working" SSB CB's for $20 each at a recent Hamfest...
Midland model 79-892, and a Cobra 138. The Midland uses a PLL-02A phase-
locked loop synthesizer to control the 40 channels, and the older Cobra uses
10 quartz crystal oscillators to control its 23 channels.
I suspect there are dozens of other brands that have almost identical design.
I remember converting a 23-chan Kraco (AM) many years ago which used a PLL.
I was fortunate enough to get service-info (SAMS PHOTOFACTS) thru our local
library....CB-180 (April 78) for the Midland, and CB-57 (Sept 74) for the
Cobra.It's a good feeling in our throw-away society, to be able to re-cycle some
of this great equipment of yester-year.
Converting the Midland is quite simple..its PLL has nine control lines
capable of divide-by-n (1 to 512). The Midland only needs to divide by 255 thru
211 for Chan-1 thru Chan-40 respectively, so that the 256 line (pin 7) is
disabled permanently (grounded). Since a division of at least 211 is needed,
the 128 and 64 lines are always enabled (tied to +5), and the remaining six
lines (pins 10 thru 15) are switched by the Channel Selector dial to progress-
ively lower the count from 255 thru 211.
These values may only apply to this model, or perhaps other Midland models....
they depend on choice of VFO and I.F. frequencies, and the down-shifted fre-
quencie offered to the PLL, which always divides-by-n to reach 10 KHz which
provides phase-locked-loop control, to force the VFO to move in 10 KHz steps.
In this particular model for example, on Chan-30 the VFO runs at 38.000 MHz
mixed with an I.F. frequency of 10.695 MHz to provide the Chan 30 frequency of
27.305 MHz. (This is a good example because for converting to the Novice band,
we will want to start at exactly 1 MHz higher...at 28.305 MHz). In addition,
to down-shift the VFO for manageable frequencies for the PLL, it mixes it with
a fixed 40.210 MHz for a difference of 2.210 MHz (on chan 30). Dividing this
down to 10 KHz requires a divide-by-n of 221....of which div-by-192 is perm-
anently wired as described above (pin 7 LO, pins 8 & 9 HI), so that only an
additional div-by-29 is needed and the Channel selector knob supplys this (on
chan 30) by grounding pins 10 and 14, and enabling (to +5) pins 11, 12,13 and
15. Pins 7 thru 15 represent div-by: 256, 128, 64, 32, 16, 8, 4, 2 and 1, res-
pectively.
As a side note, many people do not realize that below Chan 20, there are
five places that adjacent Channels actually jump 20 KHz, instead of 10KHz:
...i.e. between 3 & 4, 7 & 8, 11 & 12, 15 & 16, 19 & 20 ....all are separ-
ated by 20 kHz. The remaining channels thru Chan 40 all have 10KHz separation.
I hope all this expanded theory will be helpful in analyzing some of the
various models on the market.
GETTING BACK TO HOW SIMPLE IT WAS TO MODIFY MY Midland 79-892, all I had to

do was cut the PC-board foil to pin 8, then connect pin 8 to pin 7 (which was already grounded). Then tweak the slug on the VFO counter-clockwise to raise its frequency to 39.000MHz which raises the operating frequency to 28.305 MHz as mentioned above....but if you are expecting to receive or transmit on 28.305 MHz, the Chan selector needs to be on Chan-6. The VFO can is the largest shielded-can about 5/8" x 1 1/8"...much larger than any others...with the ferrite slug on top. Operation will not "pop in" until you tweak the VFO near enough for the dc control voltage to capture contol of the VFO. Until then, an out-of-lock signal will disable the system. You can measure the dc control voltage coming out of the PLL (IC-1, pin 5), and tweak the VFO until this control-voltage centers at about 3.5v on Chan-12 (about the middle of the Novice band) although it's not critical. If you plan to operate higher than 28.500 MHz, you might want to center it on a higher channel.

To summarize the theory of this example on the low end of the Novice band: VFO is at 39.000 MHz (1 MHz above CB-chan 30) and mixes with I.F. freq. of 10.695 MHz for a difference of 28.305. For phase control, the 39.000 is also mixed with a 40.210 MHz reference for a difference of 1.210 MHz which requires a div-by-121 to reach 10 KHz. We had to ground pin 8 to avoid a minimum count of 128 (we need 121 or less). We still have fixed divisor of 64 (pin 9 tied HI), so the selector channel needs to supply an additional 57 which it does in Chan-6 position by switching pins 10, 11, 12, 15 HI, and grounding 13 & 14.

After these two simple changes, the radio came to life immediately. However since I had the SAMS book with all the pictures to identify components, I went thru and tweaked up the circuits that now operate at higher frequencies. It did as you would expect improve considerably. Those without documentation will need to proceed carefully. The inductors near the RF Power out and its driver should be easy to identify without docs.

Finally, I also mentioned an older 23-Chan Cobra model 135. I have not changed it over yet, but in analyzing the documentation, I feel certain it would be easy to convert by simply replacing quartz crystal X10 (8.409 MHz) with one 9.5 to 9.67 MHz ...a single crystal would provide four operating frequencies. Each new crystal in that range would offer four more operating frequencies. In this model, the sum of two crytals (one from each group) combined with the 7.8 MHz I.F. yields the operating frequency.

Both models have the "clarifier" function in Receive, which shifts operating frequency plus or minus....perhaps filling in most of the gaps in the channels separated by only 10 KHz. If desired, it should be an easy task to modify this same circuit to include shifting the Xmit frequency also.

I FORGOT TO MENTION that on the Midland modification, Chan-21 on the selector yields the High end of the Novice band at 28.495 MHz. The dial limits should be marked clearly, or perhaps a physical-stop on the older dials if only the Novice band is intended.

From: hduff@humnet.humberc.on.ca
Message-ID: <7965-227002401@humnet.humberc.on.ca>
Source record: 111041

I am looking for a proven, known working wideband amplifer
design to take a DDS (direct digital synthesis) signal of a few
milliwatts up to 3 to 5 watts.
Operating range from 1.8 Mhz to 20 Mhz. The amplifier must be
stable, solid state with as low a parts count as possible.
(How's that for stingent specs !?)

I want to use my DDS as a (nearly) all-band QRP HF transmitter.
I will look after the required bandpass filtering. I've seen some
designs that will deliver the required power but not a broadband
design that will cover most of the HF amateur bands.
If you have something that doesn't quite go 1.8 to 20 Mhz, I'd still
like to hear about it !

Thanks..Hugh Duff VA3TO Toronto

Hi Jeff

Sorry, I no longer work at a place that has those data tables, but I do
remember that most NE lamps operate between 105 to 125 volts, but as you
found out their are exceptions.

The particular neon lamps you are referring to, and this is a wild guess,
are probably numbered NE83, NE86 or 5AH.
The NE83 and the 5AH are identical and their operating voltages are between
60 and 100 volts, whereas the NE86 is between 55 and 90 volts and probably
the bulb you are looking for. It's life rating is only 2000 hours and
therefore needs replacing quite frequently.

Have fun finding one! ;-)

3939. T/R switching 440Mhz brick

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-30 00:00:00 UTC
From: aswNS@hamp.hampshire.edu
Message-ID: <420cjo$9nm@gort.oit.umass.edu>
Source record: 111047

I have a little 440 Mhz amplifier that uses an integrated "brick"
amplifier that was removed from some kind of equipment (so said the
OAOAseller). I need a T/R switch to make it really usable.

I had a Heathkit 2 meter amp that did T/R switching using 1/4 wave
lines connected across input and output and connected together and to
some diodes at the other end:

```
in o-O====================-------====================O-o out
| | | |
v --- V v
amplifier input ^ --- amplifier output
| |

___ ___
/// ///
```

The idea is that the diodes effectively short the middle to ground
when r.f. is present and the 1/4 wave sections are isolated, but it is
just a 1/2 wave when receiving.

I would like to do something like this at 440 Mhz, but I don't know
exactly what design considerations I need to consider or how to test
it's really working right. I don't want to blow up my amplifier.

Suggestions would be appreciated.

I would like to place the NB-filter of my R7 after the 2.IF ampli. chain
(just ahead of the 3.Mixer) to limit the broad-band noise.
Who knows the termination impedance of this filter?
I could estimate it to about 4500 Ohm using the capacitor-transformation
ratio of the tuned circuit ahead and behind the filter. What is the
exact value?

3944. Need info on Moto Hybrid RF Power amp.

Also, get a copy of MOTOROLA RF DEVICES MANUAL (2 volumes now.) Many of
the application notes deal with solid state amps and combiners to get
larger powers out.

I'm not sure if CCI has them, but I know RF Parts in San Marcos, CA does.
Their phone # is 1-800-737-2787.

From: davek@medphys.ucl.ac.uk
Message-ID: <1995Aug30.143816.63323@ucl.ac.uk>
Source record: 111054

I've seen a mention in the VHF/UHF DX book that one can run a pair of 4CX1500B's in a push-pull configuration, like the W1SL design (which is a well known 2m amp, using a pair of 4CX250B's in push-pull, grounded cathode, grids driven). There is however no reference to a design doing this. Has anyone seen one, or no of someone having done this?

Anyone ever got a pair of 4CX1000A's running on 2m ?? Ever tried and like me not done too well?

3947. Regulations Short-Wave Transmitter/Receiver must fullfill (help)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-30 00:00:00 UTC
From: Bill <Bill@survival.demon.co.uk>
Message-ID: <164236433wnr@survival.demon.co.uk>
Source record: 111055

A UK based charity has developed a pedal powered generator to operate a short-wave transmitter/receiver working at (4.005 MHz). The use is to supply village to village communication in Tanzania Africa. A small pilot project has successfully run for the last 12
years with commercial bought in equipment. The aim is to manufacture pedal generators and short-wave transmitter/receivers locally in Tanzania both to save foreign currency and provide
local employment.

A transmitter/receiver has been designed and 95 per cent completed.

Does anyone know what international regulations such a short-wave transmitter/receivers would have to comply with? The project is based in the UK.

Thank you for any help anyone can give.

Bill

3949. more on EASY CB-10M SSB option

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-08-30 00:00:00 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.809813418@eagle.csl.uiuc.edu>
Source record: 111057

This will append the previous entry called EASY CB to 10M SSB: This offers another nice option if it is to be used on Novice band only (This applies to the Midland 79-892 model). The PLL-02A IC offers the option of moving in 5 KHz steps, by simply grounding pin #4. In this case, pin #8 does not get changed (stays high as it is originally). We need the higher divide-count to reach the 5 KHz phase reference (double the count required on 10KHz).
The same instructions changing the VFO still apply. In this case, the 28.305 frequency is not available because of the glitch in selector switch which was necessary to accomodate those "20 KHz step" exceptions. The lowest frequency will now be 28.310 which corresponds to Chan-12. (Technically, 28.300 USB on Chan-11 might be permitted, but I would not advise it). The operating frequency moves in 5 KHz steps as the Channel selector is advanced (except for the 2 or 3 glitches where it advances 10 KHz). But there are not enough switch positions to reach the high end of the Novice band so that Chan-40 corresponds to 28.460 MHz. With the smaller 5 KHZ steps, it is almost certain that the clarifier will fill in the gaps with possible exception of the 10 KHz "glitch" channels.
From looking at the schematic it appears to be a simple matter to add a "Delta-Xmit" pot to shift the Xmitting frequency during Xmit only. Replace R-26 (10K) with a 100K pot...using two of its terminals and locate the pot in a convenient location. Run a shielded line to replace R-26. Be sure to verify which end of R-26 is ground. Add a 0.01 ufd across this location. This should work well, because an almost identical circuit is used to place the "receive clarifier" pot remotely in the Hand-mike.
...One small correction in the original article....at one place in the text I mistakenly referred to a Cobra-135. It is model Cobra-138.

Gary,

In a power supply I designed commercially, I used long foil traces to generate the resistance required. Perhaps you could use long emitter hookup wires. 50 milliohms is not that hard to get either way. Another nice thing is if a transistor hogs current, the resistance of the conductor in it's emitter goes up a bit. That helps keep the current more even. Sometimes temperature instability in a component can be a blessing.

You'll have to get a Motorola data book older than 3-4 years. Q3/91
is the last of the "good" ones. They have taken out the application
notes from Vol 2 and combined the volumes together into a single data
book again. But you can request for any application note to be sent
to you still. Check out their WWW site for more info. --Mike

Many people are aware that there has been a lot of the above tubes flaoting around cheaply. Deos anyone have a data sheet, or can tell me who made em? I've been told thay are like the RCA/Burle 7213/7214, but *not* exactly the same. The data sheet on the 7213 suggest these tubes would work fine on 70cm and perhaps (at a push) on 23cm, but I gather this is not true. Above 2m is tricky, but a 1500W tube at 2m is not to be sneesed at.

The ARRL Handbook has a table of properties of copper wire.
For example, 20 guage copper wire has a resistance of 10 milliohms
per foot.

There was an article in QST a year or so ago that mentioned some of the
arc transmitters. It said the 1 MWatt transmitter was built to maintain
communications between the US and the expeditionary force in France in WWI.
I got the impression it was never put into use. They mentioned some huge
electromagnets that were built for it, that were the largest ever built until
well after WWII. They were eventually used in some Physics research project.

They also mentioned a problem with the alcohol vapor. If the door to the arc
chamber was opened too soon after the arc was turned off, the air rushing in
would hit the alcohol vapor and the still hot surfaces and cause a flash of
fire. There were cases of radiomen being killed in these fires.

Allan,

Call ICOM America at 206-454-7619, press " 3 " when the automated system answers. You will then be connected with ICOM's parts dept. They have a manual titles the " CI-V Reference manual " for sale at a cost of about $15.00 plus shipping. This manual has the commands for the IC-R7100. Newer ICOM radios now have the command set for the radio right in the operators manual so it is doubtful the CI-V Reference Manual will ever be updated

Darius,

If you don't have them, go to a library and check the indexes (December issues) of QST. Over the past three or four years, there have been several articles on this topic . . including how to build your own coaxial tuning capacitors.

You might consider the 1.8 to 54 MHz 5 watt amplifier in the
May 1992 issue of QEX. It uses a MRF 137 running off 28 volts
for acceptable IMD performance.

Neon lamps are normally ignited by about 83 volts.
However several external/internal sources can cause them to ionize with
lower voltages. Incident light, rf fields, radiation...
Some lamps have a micro radiation souce embeded in the lamp to
stabilize the ignition voltage. These are almost all lower than the 83 volt
level. The military lamps with an internal source often have/had warnings
about their disposal.

Perhaps this will help your problem in some way.

Correction to my previous posting. The standard frequency is 262 kHz.
not 252 kHz., and it's no particular relationship to 455 kHz. Does
anyone know how 262 came to be a standard IF anyway? Only thing I can
figure is it is half of 525, which is the bottom of the AM radio band.
Any lower and you'd have a nasty 2nd order crossover spur in the mixer.

Rather than building these, why not use emitter resistors, commonly
sold for use in high-power audio amplifiers?

These resistors are usually available in values down to 0.1 ohm, and
power levels of 1 watt and up. Two of these in parallel would provide
the value you're looking for.

One supplier to check is MCM Electronics in Centerville, OH. Their
number is (800) 543-4330, or for product questions, (800) 824-8324.
They also offer a free catalog.

The "X" in the part number means it was designed and manufactured by Motorola Japan. Not Motorola USA. If you call Motorola in Arizona, they will deny that such a part exists. I know from past experience with a different kind of part with an "X" prefix on the part number.

However, If you persist in asking for other departments in the Arizona facility, you may eventually come across someone who will admit to knowing about the part and can send you a spec sheet. I can't recall the name of the individual I finally talked to, but he was most helpful; all the while claiming that he didn't know anything about it.

Hope this helps a little.

Regards,

Lewis

We tried to approach Murata about custom ceramic filters and they wouldn't
give us the time of day. They simply don't do custom filters, period, no matter how
high your volume. They only make filters that would be of general interest
to many customers.

If anyone else knows where we can go to get custom filters, please let
me know. I am specifically looking for 10 MHz. (not 10.7 MHz).

BTW, on your 240 kHz. filter: did you realize that 252 kHz. is a standard
frequency (it's half of 455)? Both Toko and Murata make that one.
If you can QSY from 240 to 252, you're in business.

The circuit is a little more complicated than that with RF chokes and DC blocking capacitors but if you use PIN diodes such as Motorola MPN3404 (which is pretty cheap) and mind the velocity factor of the coax to calculate wavelength, the circuit will work fine up to a few 100 watts.

I am interested in purchasing old mechanical calculators and slide rules.

I collect the old electro-mechanical "rotary" calculators that were made by Frieden, Marchant, Monroe, and other manufacturers from the period of the 1920's through the late 1960's. I also collect non-electrical mechanical calculators and am particularly interested in Curta brand calculators. I am not interested in adding machines that print on tape or electronic calculators.

If you have an old mechanical calculator or slide rule collecting dust in a closet, please send me an e-mail message.

Jonathan -

Normal practice for "hidden foxes" is as you surmise - use a commercial HT (like your old Icom) with some sort of controller. There are controller kits available from time to time which are usually somebody's kitchen-table project, but I can't readily tell you what is available today.

There was an ID'er/controller featured in the July (I think...) issue of "73". It was a very simple design based on a PIC uP, and you would buy the kit with the callsign already burned into the chip. It would be legal and usable for foxhunting.

It is particularly important in "beginning" foxhunt programs to make sure the fox transmission has some content to it to make sure it can be distinquished from QRM/QRN. Obviously, it needs to be in FM to be sure that you can draw from the largest potential field of hunters. A low-power unmodulated CW carrier will be difficult to hunt unless your hunt area is very limited, and keying the PTT for true CW ID might be pretty rough on the HT.

I will advise against Mike's idea of putting the fox in the beacon subband. Other users of this area are expecting true CW and/or SSB, and your operation of a "mystery beacon" during a coincident band opening will upset the weak-signal users who depend on this area. Also, FM operation (even if just a MCW ID) is not appreciated there.

There has been a long-standing suggested national foxhunting frequency of 146.565, which we use on hunts that are not through the repeater. That should be a good starting place, though most of the recognized voice simplex channels in your area (but not 146.520!) could be used.

Funny story. A teacher who just happened to be a ham taught a
short intro electronics class when I was in sixth grade. The feature
project was a tiny transmitter for jamming TV bcasts. He'd instruct
us to mount it close to the twinlead and turn it on (this was long
before the advent of cable).

Of course, he suggested that we offer our services to fix the problem,
which consisted of sneakily recovering the jammer and subsequently
giving the neighbor a few good lines of techno-babble describing the
problem. Thus demonstrating our electronic prowlness and "kindness". <g>

Well, this is just a thought. If you know anybody in the two-way land mobil business you may want to give him / her a jingle. I worked in 2-way radio about 15 years ago and I have clear reccollections of there being a cross reference guide that cross references standard parts (2Nxxxx, etc......) to Motorola in house numbers. I also remember seeing a web page for motorola. Mabey you can get somewhere there.

Unfortunately, I don't think there you will find a cross referecne for the high band part you posess. I reeks of a very 'custom' part. The last high band "brick" I remember that Motorola made was a MHW-252, and that was back in the 70's, I think. In the mean time, I'll check with a couple of my buddies in the biz, and see what they come up with. Good luck to 'ya.

3992. TEK 491 SPECTRUM ANALYSER

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-01 00:00:00 UTC
From: P.Dalliessi@massey.ac.nz
Message-ID: <P.Dalliessi.117.30465383@massey.ac.nz>
Source record: 110901

Desperately need help with a Tek. 491 spectrum analyser problem.
SA works fine on all bands. Problem is in the "LOG" mode, the on screen dynamic display is far from linear. e.g., a -35dbm signal set on log. ref. at top of screen, shows -25db after 20db of attenuation is switched in, whether by the internal IF attenuator switch, or using an external attenuator. This effect is even more pronounced as the signal is attenuated nearer the base line. The problem does seem to be connected with the log. video detector.

Is there a Tektronix engineer out there, or someone familiar with the 491 who could help?

I would appreciate a direct "EMAIL" reply, initially, and we could then continue on the netnews for the benefit of others who may have a similar problem.

Thanks in anticipation.

Peter Dalliessi, ZL4MS,
FIMS,
Massey University, Palmerston North,
New Zealand.

I have a Kenwood tr-7950 that does not have the optional tu-79 tone unit installed. Kenwood says that option is no longer available. does any one know of a way to build one? The local repeaters are all using 100Hz tones, so thats the only one I will need.
Any info about how to make one or how to modify another unit to work in the 7950 would be appreciated.

Thanks,

Butch KF5DE

Butch, It shouldn't be that hard to put in an aftermarket tone board.
The factory board will only let you set it up for three different
frequencies, if I remember correctly. If you only need one frequency,
I would look at one of the miniature tone boards that Communications
Specialists sell. They are available from a lot of the mail order
places. They are very simple to hook up. The original factory tone
board plugged into a small plug on the 7950. My guess it was a B+,
GND and tone into the radio line. Even if it is not, you can call
Communications Spealists and they will tell you where to connect their
boards on most radios. I hope this helps....73's Floyd WD5ENJ

I am a little fuzzy on this, but there seemed to be a shareware program out there from Germany called HAMCOM. With it, came a schematic that had a simple bridge rectifier that would provide +/- 12volts or so from the CTS & RTS lines. The 'guts' of the circuit was just a little op amp that was set up as a comparitor, thereby acting as a limiter & level translator. You do not want TTL levels, you need RS232 which is a bipolar, or +/- level signal. (Unless you are using an old Comodore, which does use TTL levels on a psuedo-RS232 port). Alternately, you could use 2, 9 Volt batteries to power the op amp. Hope this helps.

3999. multiband mobile HF antenna plans wanted.....

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-01 00:00:00 UTC
From: edbu@sepia.wv.tek.com
Message-ID: <427rgnINN60c@sepia.wv.tek.com>
Source record: 110908

I saw a particular antenna design at the last Ham swap meet I attended
which used a loading coil mounted on a motorized threaded shaft which
was used to tune the antenna. The whole thing was housed in a 4 foot
section of 2" pvc pipe. You had to supply your own whip antenna
for the top, but this thing would tune up on any frequency!!
If I remember right, the original design was done by a guy named
Don Johnson.

Has anyone seen plans or an article on how to build one of these?
Any pointers would be appreciated.
Thanks,
Ed Burress

Thanks for your comments, Pat especially those pertaining to the type of input I need to the computer.

The op amp circuit you describe is not the one I am after. That is a "comparator" type demodulator and feeds a squared up audio signal to the computer where the software does the rest of the job. This works quite well for SSTV and (I am told) fairly well for RTTY, etc. However I want to do the frequency to voltage conversion outside the computer and feed some really promising software for the commercial and amateur TOR modes.

Use Nichrome (Nickel/Chromium) alloy wire. It is a fairly high resistance wire
(don't remember the ohms/ft) used for winding resistors and heating elements.
We used to use it for model rocket engine ignitors. Back in Jr high school, I
borrowed a few yards from the lab. I'm sure you can get it from elect.
suppliers.
One problem is you cannot solder to it. Screw the ends to a barrier strip.

4004. Motorcycle intercom

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-01 00:00:00 UTC
From: it@scimitar.dolphinics.no
Message-ID: <4277jn$lbg@oslo-nntp.eunet.no>
Source record: 110913

Hi,

I would like to build a motorcycle intercom that transmits in the 46Mhz range. This range is used by illegal cordless phones in Norway, so I shouldn't interfer with a critical band.

Since I only need a range of approx. 300m, I'll probably only need a few milliwats. I know how to build the microphone preamplifier, a VOX and the FM receiver part. But how do I build a fairly frequency stable transmitter stage using a xtal based oscillator? In other words: how do I get from the audio signal to the antenna?

It is almost impossible to find litterature in Norway covering these issues. Please help me out. If you know where to find schematics (books or on the Web) I would appreciate that information.

Thanks,

Ivan Tving

Ok...thanks a lot for the postings and the E-mail. The AM7911 and EXAR XR2211 sound most promising.

Just to clarifiy for those who questioned me. I do use a PK232 and also some small homebrew comparators (Jan'94 QST) but the object is to feed some software with especially broad capability for examining and printing a wide variety of commercial and amateur TOR transmissions.

Since there appears to be some interest I will post my results along with the software source if/when I get permission to do that and/or it becomes commercially available.

Thanks again.

4008. DJ580T mod question

I am atempting to do the extended receive mod. on my DJ580T. I know
that you are supposed to cut the red wire, but I want to make sure
which wire you cut. With the unit's display facing up and the bottom
removed you can see a "red" loop wire that is about the same size as
the blue one, and then there is a small "orange/red" wire at the top.
I believe I cut the larger loop which is red and not the smaller loop
that is orange/red. If anyone can clear this up for me I would greatly
appreciate it. Thanks and 73.

Oh, I understand now. I guess what you are seeking is a true demodulator part of a MODEM. Sorry, I can't be of much help in that area. I am no expert when it comes to hf modems, but I have grabbed a few files from here and there on the subject of hf modems. I would probably atttempt to build a simple one for myself for RTTY, but when you get into some of the more complicated hf modems & techniques, things get a little more difficult. I am pretty much completly ignorant about SITOR, AMTOR, GTOR, PACTOR, etc..., other than the fact that they exist. My guess is that the prices of multimode hf modems reflect the level of sophistication contained within. If I had to guess, I would say that the day of the simple analog band pass filter, followed by a frequency discrimator /detector/flip-flop have gone the way of the dodo bird, hoop skirts, bobby sox, and big fins on Caddilacs. With the prices of DSP products being what they are, and the capabilities of DSP, I would boldly guess that this is what will be used for all types of modems in the future, if not already. Trying to duplicate this function with discrete parts would be quite a chore. I mean shucks, you can go to Radio Shaft, and for a few bucks, come home with a simple, functional automatic notch filter that uses digital filtering techniques. Granted, it's not the best, but try and duplicate that in the analog world. Possible, but not easy. When I finally get around to fiddling with the RTTY & related modes on hf, I think I'll just take the lazy mans way, buy a box, and plug it in. Even a bad one (MFJ) will probably work better than one that I spent 100 hours building and troubleshooting.

Good luck to 'ya Rudy(?) Happy motoring.

Yup - that's probably just what Rudy is looking for. I myself haven't seen an Exar data book in years, but I do have a dim reccollection of that being a PLL type of device. Is that correct? Are they still around? I wonder, just how well did that work under normal hf conditions, that being noise, fading, phase distortions, etc....? Ever since I got this computer that I'm using this very instant, I have been getting more and more anxious to get it hooked up with the hf station. It seems there could be some software for the soundblaster thingy to allow one to maybe demodulate RTTY and SSTV. Whaddaya think?

4020. HTX100 schem or transverter mods??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-03 00:00:00 UTC
From: landisj@nad.com
Message-ID: <1995Sep3.170708.359@nad.com>
Source record: 110829
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi,
Does anyone have a schematic for the Radio Shack HTX100 10 meter rig,
or has anyone added seperate low-level transmit and recieve?
I'd like to use mine for a 28mhz tunable if for a DEM 432 mhz IF transverter.

Thanks,
Joe - AA3GN

I can't speak for their SW radios, but the service manual for my
HTX-202 was very complete in that regard. Cheap too--compared to the
Yaesu one for my FT-530 at $25, RS only wanted $6.59 for this one.

The part number would probably be MS- followed by the catalog number
of your radio. The best thing woud be to take the radio to a store
and tell them that you want a service manual for it. If the
salesperson looks blank at that, ask him/her to call Consumer Mail and
ask for a service manual... (They may be calling it Radio
Shack/Unlimited by now, I'm not sure). If the person _still_ doesn't
have a clue, ask for the manager, but it's really not too hard.

4022. Power Supply Question...

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-03 00:00:00 UTC
From: danb@a.crl.com
Message-ID: <42bhkb$iob@nntp.crl.com>
Source record: 110831

I've recently come into possession of an (apparently) old power supply, and I'm wondering if anyone might have info on it.

The nameplate reads:

POWER SUPPLY
MODEL

(stamped) OEM 10E P 1912 (may be 1942)

INPUT 105-125V., 47-429 CPS

POWER/MATE CORP.
Hackensack, N. J.

It measures about 5" square by 9 1/2" long, and is labeled "REGULATED POWER SUPPLY" on the front, with a pot for voltage adjustment. AC input, DC output, and "Sense" (+ and -) are via a 6-position barrier strip.

One transformer occupies the back half of the unit; another, smaller, one is nearer the front.

I'm wondering (1) what the voltage/current capacity of this are (I expect large; the thing weighs a ton), (2) if the company's still in business, and (3) anything else that might be useful. Thanks for any information!

FREE - NEW Macintosh HAM TEST SIMULATORS

Studying for a ham test and have access to an Mac?

Upgrade Fast! Simulate the test and get S T I M U L A T E D!

Scores of 90% or > even get applause!

The new Macintosh Ham Test Simulators are HERE (and there if you can FTP)!

o Novice Ham Test 5.0 SA.sea
o Technician Ham Test 5.0 SA.sea
o General Ham Test 5.0 SA.sea
o Advanced Ham Test 5.1 SA.sea
o Extra Ham Test 5.0 SA.sea

The latest version "5" feature:

HyperCard 2.3 as a stand-alone application (SA) eliminating
your need to have HyperCard. All you need is a Mac with 4
Meg of memory and version System 7 or greater.

Each version "5" Ham Test Simulator has the latest questions
as prepared by the Question Pool Committee.

Each version "5" Ham Test Simulator is FREE OF CHARGE and work the
same way as the originals did (written by Diana, KC1SP).

You may obtain a version "5" Ham Test Simulator by mailing me a *FORMATTED
disk (1 per test) and include a Self Addressed and Stamped disk mailer for
the return.

Each version "5" Ham Test Simulator is also bundled with a shareware CW
program called MacMorse 1.4 written by Doug, WB0EON.

Also included in the version "5" collection are text files that relate an
interesting variety of ideas about the best way to study CW and prepare
for tests.

Or warm your phone line and get JUST the tests:

America On Line - Macintosh Ham Radio Section

or:

ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/AdvancedHamTest.sea.bin
(Aug 30th)
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/ExtraHamTest.sea.bin
ftp://oak.oakland.edu//pub3/hamradio/mac/theory-and-morse/GeneralHamTest.sea.bin

They closed their doors in Hacensack NJ about 87' or so and moved to California. I'm pretty sure they are completely out of business now. I worked as a power suply design engineer for them during the early 80's.

10 volts @ ????A....sorry, I don't have much info on the current rating or how to decode the date code. They made some pretty good OEM supplies back in the late 70's. I have several 12 and 15 volt 40 amp models here that have been powering my shack for 15 plus years without repair. Hope this helps....

I ordered the service manual last friday. Twelve bucks and it will be
mailed to me. The lady at R-S knew exactly what I wanted and even
remembered 90% of the part number for it! A quick call to wherever,
resulted in a full part number and price.

Say what you will about "Radio Shaft" or "Radio Schlock", I have found
that generally I get very good service. And I've found one store that
will get *all* my R-S business.

>Definitely a different kind of 'homebrew'!!! ;-)

Definitely an interesting concept, though.... <grin>

I mean think about it.... I'm assuming (at least, in a humorous and
not-so-serious sense), from where the original poster placed his article
and from the kit's name, that this Mr. Beer kit is an Amateur Radio kit
that works as a radio and also dispenses and/or brews beer.

This could really be a neat thing---it combines two of my hobbies into
one nice, neat package, and could be fun for long nights of operating,
too. Just picture it...you're in the middle of a nice chat with AMTOR,
PacTOR, or cw (or whatever modes you prefer), and you draw a nice, fresh
IPA, bitter, bock, or even a nice oatmeal stout right straight from your
radio. Saves a trip (or trips) to the beer fridge! :-)

Hmmmmm.....I wonder..... <grin>

You are right the designer is Don Johnson and the design is published in a book he wrote "40+5 Years of HF Mobileing. It is available from World Radio Books for about $15.00 or so. The design may be published in other places also but I don't know of any. There are also several commerical sources of the antenna one of which is Hi Sirrea who along with others adverise in QST and probabbly other places. I recomend the book as its a very nice bedside reader and tells of many designs over the years.

>I was going to buy this $29 FM Transmitter, but I then I realized it only

>transmitted a few feet. I've seen some FM transmitters that do 3/4 of a mile,
>but that don't have stereo line in with dual speaker separation.

I used to build surveillance FM x-mitters for private dicks. That was fun. You need a stereo x-mitter? Ramsey electronics makes one.. I picked one up at a ham fest and put it together in an hour and a half. A no brainer, plenty of
room to work on the board (no tiny SMT parts) I looked for their address I can't find the papers. Look in the hobby mags. The heart of the stereo xmitter was a vlsi chip that did all the multiplexing for the stereo FM modulating
of the free running oscillator with only one next stage of amplification really
acting only as a buffer. the output goes to an antenna through a 75 or 100 ohm resistor. I removed that to get a bit more range. As you can imagine the
FCC would not appreciate a substantial amount of amplification from any transmitter whose frequency stability is derived from a FREE-running oscillator.
(licensed or not) My Ramsey stereo FM transmitter works like a charm. I built
a MONO one in the late 70's which I brought to the beach with me to play Black Sabbath over the crappy disco stations - DEATH to DISCO!!!!!!!
Pirate FM lives! (at least within a 500 ft perimeter)
You can do it yourself, save your 65 bucks to buy it. I think it was less than that to buy it. Let me know how you made out and/or if you need any help.

Get a "junk box" 3,579.5KHz colorburst crystal. Make an oscillator using a 9v battery. Connect a 3ft piece of wire to an RF hot-spot on the ckt and run it down your pant leg. If they notice the TV goes wacky evertime you enter the room they will put you in charge of the fridge detail in the kitchen during playtime.
p.s. With the colors going wacky and after a few buds both teams will look the same and you'll just enjoy the pretty colors. As an alternate you can become MR. POULARITY in your neighborhood by calling CQ on CW at full legal limit
during the last quarter on that 80mtr frequency!

I built one that keyed the ht and sent CW tones into the audio mic line. The keyer can ID my call only as it is diode programmed. A better way is simply to use a 555 chip for the key timing and the new vioce recording chip now carried by Radio Shack. you ca get up to 20 seconds of audio. I was thinking of making a simpex repeater with 2 or 3 of them cascaded. You can record a taunting audio message to all those wandering plebes! I place my "bunny" in a military shell box, painted it camoflauge and had drilled a small hole for a BNC connector onto which I made a thin stiff wire antenna painted black with some twigs and leaves twisted around it taken from the spot where it was hidden. It was in a bush "protected" by a catapillar nest off in a god-forsaken corner in Floyd Bennet Air Field in Brooklyn. It was found after 2 hours. If you can take advantage of a radio's HI/LO setting by keying that randomly too. You can also mess up those phase sensitive arrays by horizontally polarizing the signal. Placing a hidden wire reflector or director neaby can also "tax" one's expertise in such an effort. Have no mercy let them suffer.

I know grounded screen can be used, but I've never seen anything push-pull grounded screen. I've had some trouble doing this, and woder if there are any known problems (and hopefully solutions).

Hi Dan,
Dare I suggest you just test the output? Look for voltage sag with
increasing load. My guess would be when it's down 10% your at the limit.
Also the supply may just shut down with too much current.

THis is the company that built really stupid adjustments on some of their
supplies... like don't use a metal screwdriver, if it contacts the case,
boom!

My boss at MIT refused to sign any purchase orders for their products,
for this reason.

Feel free to E-Mail any questions.

Tom

From: majec@bga.com
Message-ID: <42f53e$dut@giga.bga.com>
Source record: 110852

I have an ft101ex and I am working on the now deaf reciever. I found that q2 on the IF board is dead. The manual calls for a 2SC784r. What is an easy to find replacement for that transistor.

I am new to homebrew/breaking radios but I enjoy tinkering. Also I wonder who is the manufacture of parts useing the "2SXXX" prefix.

My question is, what is an easy to find replacement transistor. Will a 2222 work or how about a nte 123ap. I have those on hand.

Q2 (2SC784r) is the second IF amp after a jfet Q1 (2SK19gr).

Any help is appreciated.
Thanks

Has anyone built any of the QRP transmitter kits by Ramsey? Are they mostly just for the fun of building or do they actually perform reasonably well? If the adage "you get what you pay for" applies, then I wouldn't expect much performance for just $30.

Yup, if you can find a store that hires good people and trains them right, you got a good one.

I went into a RadShack and asked for a manual and was told they do not sell them to the general public. When asked why, I was told it was because they don't want to be responsible if someone modifies a piece of equipment to do something illegal, or hurt themselves fixing it.

A call to the District Manager solved that. all in all, RadShack is a good deal, if you can stand the high prices...

I've purchased several service manuals for RS products over the years ranging from a laptop computer to a DVM. I've done this atseveral stores and never had a hitch. The only thing is that they require you come into the store and pay in advance and the service manual is mailed directly to you (from Texas I assume).

I recently found out that I can order directly from Radio Shack by calling 800-THE SHACK (800-843-8422). If you have the product catalog number (usually right on the product) they can generally find the listing for the service manual if one exists for sale. They take over-the-phone payment with major credit cards (including their own Radio Shack credit card.)

> it takes > 2A at 7.5V, but I can live with it. :)

David...
In general, Motorola uses the "X" to indicate experimental pre-production parts. You will see this on everything from microprocessors to RF modules.
If you replace the X with an M, this is normally the real production number.
Most of these moules ar enow obsolete, except for a few Cablevision buffers.
I can find no reference to this device in any Motorola RF data book, but my oldest is 91, so possibly it exists in an older issue.
The power/output pin outs seeme to be consistant, so I would just power it up, and see what happens. Start at 12VDC.

bye for now,
walter

You may want to try the NN1G SWL-40 kit. I just built 1 last month. $50 and you supply knobs, connectors, and case. It puts out 1.5W on 40M (or 30M). Receiver is singlle conversion and pretty decent. All parts on 1 board.

There was a write up in November 1994 QST, page 37. Kit can be ordered from Dave Benson, NN1G, Small Wonder Labs, 80 East Robbins Ave, Newington, CT 06111.

Some of the radio gadget places in the US sell wireless transmitters that are very small. Go to an electronic store and browse thru some of the books and see if there are some ads there for such devices. In the US they are fairly cheap and easy to use, just connect to power, microphone and antenna. They usually have an accompanying receiver, too.

You might also try ordering directly from Tandy National Parts in Fort Worth, Tx. Their number is (817)870-5709. I bought a PRO-2006 manual from them a while back for $7.95. I would compare this to buying from your nearest Radio Shack Store. By the time you pay shipping from Tandy National Parts, it may be cheaper from your local store.

>Push pull operation

Call me soft hearted, Tom. But the thought of anyone spending time to build up a pair of 4CX1000'a in push-pull and then watching the fireworks when they turn them on was just too cruel to allow. Got me to thinking about an old Gates rig: the FM-5B. Had a pair of 6076's in push-pull. The tubes didn't have much gain at VHF so it wasn't too awful. So they took the same idea and put a pair of 4CX15000's in push pull. Called it the FM-20B. Oscillated wonderfully on 27 MHz. And every time it did the repair bill was about two thousand bucks. The rig used screen neutralization with bread cutters in parallel with each screen bypass. When it oscillated the RF current in the screen circuit would be so high it would turn the aluminum plates on the caps soft and, over time, they would bend over into each other.

Who was that kid over in Cleveland with the pair of oscillating 4-1000's that had a Nike missle target-acquisition radar shut down? K8RRR?

Larger audio/video service companies stock numbers like that. They buy them from companies like MCM Electronics and Consolidated Electronics (CEI). These are Japanese numbers, and both the 2SC784 and 2SK19 (fet) are very common. The 2SK19, in fact, was used in thousands and thousands of stereos as a good low-noise device for FM front ends.

Reputable shops don't substitute these parts, they use identical Japanese numbers, or worst case, Japanese replacements. MCM and CEI also sell data books covering 2SA, 2SB, 2SC, 2SD, 2SK and 3SK (mosfet) devices. The same shop that stocks the transistors should have a copy of those books to look up devices. If they don't, you're in the wrong place.

ANTENNAS AND STATIC ZAPPING

From: F048@MUSIC.FERRIS.EDU (Tim Deady)

I found that the only thing that had been fried was a Field-Effect
Transistor labaled Q1 [See next note. Ed.] on the circuit board (this
is in a DX-390/Sangean 818 mind you, other models could be different).
I replaced this with an MPF102 FET that I bought at Radio Shack for $.99
(Cat. No. 276-2062) and my radio has been working fine ever since.

From: Mike.Stine@f239.n109.z1.fidonet.org (Mike Stine)

Your message mentioned zapping the front end of the Sangean The front end of the Sangean 803A/DX-440 has a FET which will blow. Its Q115. Radio Shack used to sell the part which you can use as a replacement, its MPF102 and sells for 79 cents (US).

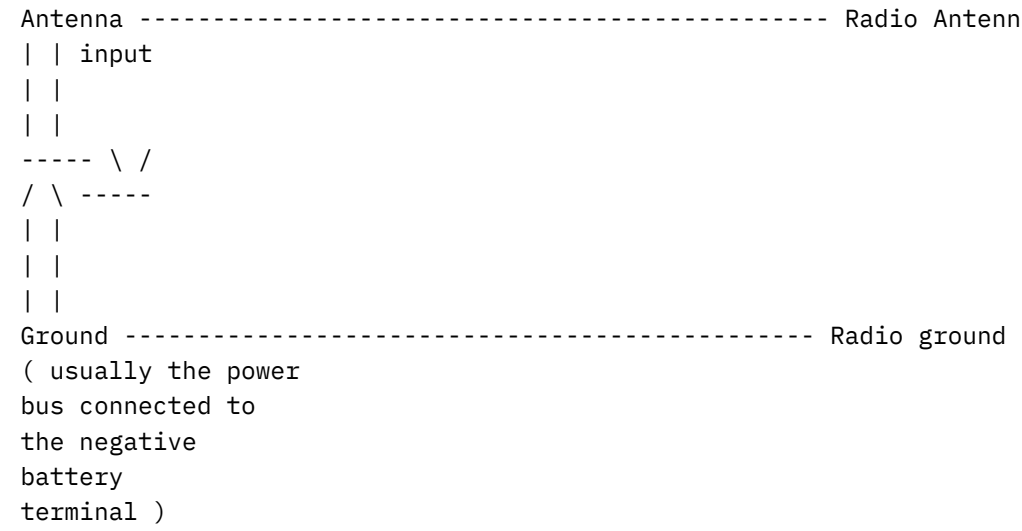
WARNING! Some receivers (Sangean, early Sonys, etc) do not have overload protection for reasonable voltage transients on external antennas! Put back-to-back diodes in parallel between the external antenna lug and the external ground lug on the radio. Most any silicon diodes will do. Then your front end FET won't burn out as easily next time. (This includes damage from static electricity when you touch the antenna terminals in the dry wintertime.)

From: jfeng@VNET.IBM.COM (Joseph Feng)

>is there any way to prevent the damage in the first place?

I would use the technique that is described for the Sony 2010: put a couple of paralleled back-to-back diodes between the antenna lead and the circuit ground(usually the same as the negative battery terminal). This method has a wide applicability beyond just RF front ends.

Suggested diodes are 1N914/1N4148, available almost anywhere including Radio Shack. The circuit can be found in the 2010 mods that get posted occasionally. I have no evidence that it works for Sangean radios, although the principle is well-known.



From: zlau@arrl.org (Zack Lau (KH6CP))

Perhaps the most cost effective solution is to ground the antenna through a high value resistor, perhaps 470 ohms to 10,000 ohms. This will drain

the charge while not noticeably degrading reception. The resistor wattage isn't important, 1/4 watt is a common value. A 1000 ohm 1/4 watt resistor might be a good value to ask for.

Basically, static electricity accumulates on the antenna, and it discharges through the FET. The resistor drains the charge, preventing the voltage from building up.

From: mikelson@sys6626.bison.mb.ca (charles mikelson)

I took it to a local Dealer , who said "I was lucky it wasn't worse"
as it turned out it was easy to fix:
Just remove the batteries until all capacitors discharged I haven't had any problems since.

From: WhiskerP@lgwct.logica.com (Peter Whisker)

I posted an article a week ago about how I thought my DX-440 had been zapped. Thankfully, when I opened it up, all that had happened was that the wire had become detached from the whip antennna. Phew! All is now happy again!

>
>Tom Snyder tsnyder@mail.fgi.net

I can say from experience that every kit produced by Ramsey functions exceptionally well for the cost.
No, Ramsey is not comparable with Heathkit, but then if Heathkit were still manufacturing Amateur Gear, the kits would cost about double of an assembled Kenwood product.

Most Ramsey products are documented such that the experienced builder can and in many cases modify the original designs with higher quality components or options not offered by Ramsey. I feel their concept is to provide the very basics of each kit at a very reasonable cost. For example, I have built upwards of 36 of their two-meter amplifier kits. Building the same unit from scratch will cost almost double. The RF transistor alone costs over 40 dollars at most supply houses. Even with access to discount supply houses, the cost is still over their kit price.

As a rule of thumb, you can usually figure every Ramsey Kit is going to be missing one or two minor components and in rare cases one of the major components. In order to produce the product and have it retail for such a reasonable price, I am convinced they use blind orangutangs to package them.

Gary

Hi Ed

No the transistors you mentioned are not compatable, however, the
replacement numbers for those you have shown are readily available and very
low in cost.
The 2SC784r is replaced by ECG 229 cost between 1.88 and 3.13.
The 2SK19gr is replaced by ECG 453 cost between 1.53 and 2.55.
The ECG 229 is a normal stock item, however the ECG 453 may be ordered.
PS - the low price is considered retail and the high price is list price.

Date: 1995-09-05 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Sep5.144418.98362@ucl.ac.uk>
Source record: 110722

I've a circuit diagram that specifies a type DM-15, 500pF, 500V silver-mica capacitor. Anyone know what a type DM-15 is ????? More to the point, where can I get them from - preferably in the UK, but a foreign source will do, if I cant get them here.

The circuit specifies a lead length (1/4") to use on these caps to resonate at 144MHz, so substituting any old 500V, 500pF silver-mica cap may not be wise.

: Jonathan -

: Normal practice for "hidden foxes" is as you surmise - use a commercial HT
: (like your old Icom) with some sort of controller. There are controller
: kits available from time to time which are usually somebody's
: kitchen-table project, but I can't readily tell you what is available
: today.

Another less expensive (?) approach is to use a dual-band HT and cross band it. The one I use is an FT-470 and it works quite well although it does seem to only cross band using low power.

<snip>

: It is particularly important in "beginning" foxhunt programs to make sure
: the fox transmission has some content to it to make sure it can be
: distinquished from QRM/QRN. Obviously, it needs to be in FM to be sure
: that you can draw from the largest potential field of hunters. A low-power
: unmodulated CW carrier will be difficult to hunt unless your hunt area is
: very limited, and keying the PTT for true CW ID might be pretty rough on
: the HT.

We have found beginning hunters are sometimes reluctant to go onto regular hunts so I started a beginners T-Hunt to address that problem. The hunt is on foot located at a local park. We start out with some instruction that is followed by (usually) two hunts. The first hunts were using HTs only and people were shown how to use body fade to get bearings. We also showed a couple of methods to attenuate the signal including tuning off frequencey, sliding the antenna on the BNC connector, and removing the antenna completely. We are fortunate in having L-Tronics here in town and they have been provide several L-Pers to play with as well as providing instruction. Not exactly inexpensive equipment, but great for finding the T :)

<snip>

: There has been a long-standing suggested national foxhunting frequency of
: 146.565, which we use on hunts that are not through the repeater. That
: should be a good starting place, though most of the recognized voice
: simplex channels in your area (but not 146.520!) could be used.

We generally use 146.565 but 146.520 has been used occassionally as
well. Of course, low power was being used!

>One problem is you cannot solder to it. Screw the ends to a barrier strip.
>Joe - AA3GN

A better choice is Manganin wire. You *can* solder to it, and it has a very
low temperature coefficient of resistance. It is almost as high resistance
as Nichrome.

Manganin wire is available from Lakeshore, (lsci-sales@bronze.coil.com)

4064. wanted: triodes for AN/APR-4

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-05 00:00:00 UTC
From: sbutcher@molbiol.ox.ac.uk
Message-ID: <1995Sep5.165528@ania.path.ox.ac.uk>
Source record: 110726

Hi,
apologies if this is not a brilliant place to post..... but hopefully we are ok.. I tried .audio.tubes but was directed here.

we are looking for some triodes to replace some damaged a couple of days ago.

(1) triode 9002 miniature 7 pin

(2) acorn triode JAN-955

we need 2 of (1) for tuning unit TN-18/APR4, and 1 of (2) for tuning unit TN-1B/APR1 for a 1943 AN/APR-4 receiver. Any pointers to where to find these, preferably in the UK would be very gratefully received. Everything else is working fine. If you are passing through, said receiver is currently on display at the IEE 100 years of radio meeting .
replies to group (if deemed appropriate) or email or to Peter Butcher at the IEE meeting (next to the BBC stand) :)
many thanks in advance
S

4065. Re: Ramsey Kits

>>I wouldn't expect much performance for just $30.
>>
>>Tom Snyder tsnyder@mail.fgi.net

I teach a communications class for graduate students in management curriculums here at NPS. I require a class project and one of the options is for the students to get a no code tech license and build a kit. Many of the students (who have never seen a resistor, etc.) choose to build Ramsey kits and over the past three years I have seen about 50 FM stereo transmitters and 2m and 6m transmitters and receivers. The students have always been able to get them to work and their complaints, if any, are that there is a part or two missing (Ramsey always sends the missing parts), and that they had trouble determining what some of the componets were (I have had students ask how to tell which lead is which on resistors, etc.).

Thus it is my opinion that anyone could build any of the Ramsey kits and that they will work. The smarter and more experienced one is, the more likely you are to want to modify and improve the kit, but they all seem to work as specified.

From: ibmdelf@aol.com
Message-ID: <42i6e2$88s@newsbf02.news.aol.com>
Source record: 110728

I'm looking for a replacement IC that is the control chip in a Sear garage door opener. The Texas Instrument ID on it is CX8544 (16-pin DIP). It took a lightning hit and it's got to be replaced. The rest of the control board checks out. None of the usual parts houses lists it. I'm thinking it might be a special chip made to order for the real manufacturer of the opener.

Any ideas on this one?

Thanks,
Del, KD4B

I have heard of screen neutralization before, but it has been a very long while. Isn't this kind of a cheesy way of neutralizing? Sure sounds like a real PITA to adjust correctly. I am not any kind of an amplifier builder,but I did work on some old GE and Motorola tube amps back in my two way radio days. The GE's had feedback from plate to grid, a real snap to tune up.

Hi Rick,
But it doesn't matter if the resistance drifts, so long as it drifts up with temperature. Actually copper wire will reduce thermal runaway, as temperature rises the resistance goes up and current in the hot device decreases! We used special zero or low drift materials like maganin for meter shunts and shunts for current limiting sensors, but it is actually counterproductive in this application..

Source record: 110870
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.misc

Most of these miliary rigs can be "converted" to NBFM by placing a series resistor in the mic audio line. This provides a lower amplitude to the modulator, and hence reduced deviation. Start with a 5K pot and a deviation meter, and see if this works for you. If all is well, install a fixed-value resistor in the mic.

How do one build a mono-pole antenna shorter that lambda/4 that has a
75ohms impedance matching?

I need an antenna for portable equipment that transmits and receives at
approx. 48MHz. It is inconvenient to use a dipole and it shouldn't be
longer than 10" (25cm).

If I put a coil in series with the antenna, it should be possible to
compensate for the shorter length. How do I determine the induction
of that coil?

Since it is not a dipole (and I can't use the earth as reflector) how
do I "emulate" the second half of a dipole? Can a LC network between
signal ground and the base of the antenna do the trick? How do I calculate
the LC values?

That was a lot of questions. I'll appreciate all replies.

Thanks, Ivan Tving

>Jim N6OTQ

While you can "get by" with this method, it is a very poor one. Two
things are being ignored. By dropping the audio input, you will never
reach the level where clipping or compression begins and will lose
considerable average level. Second, you are doing nothing to narrow
the receiver to the expected signal. Adjacent channel problems
can/will come up, as well as poor audio recovery from the received
signal.

Installing narrow IF filters and changing a few components in the
detector circuit, can improve the situation considerably. In some
cases, you might be able to just turn the deviation pot down on the
transmitter and get by with it.

ptracy@aol.com (PTracy) wrote:
>I have heard of screen neutralization before, but it has been a very long
>while. Isn't this kind of a cheesy way of neutralizing?

It depends on how it's done. All our tube-type commercial FM transmitters above 5 KW use screen neutralization. It is very, very effective and works wonderfully. Because the screen inductance to ground is used to provide the voltage to accomplish neutralization, it is absolutely essential that the inductance be just right and well distributed. The frequency range of an FM transmitter is only +/-10% from the center frequency. So its fairly easy with big tubes. A bigger tube with too low a self-neutralization frequency or smaller tubes with a very high self-neutralization frequency don't lend themselves to this technique. At the 5 KW level, where the tube is smaller, Bruene neutralization is the best choice.

Back in the bad old days there were some cheesy screen neutrazation circuits. But, done right--and done with the right size tetrode--its the best.

Screen neutralization is used when the self-neutralization frequency is below the desired operating frequency. The screen inductance is series-resonated to ground the screen. Obviously, this is effective only over a narror frequency range, which opens up the possibility of instability at other frequencies. A common problem with the myopic design method <g>.

I assume that the GE radios you speak of were push-pull designs. These are easy to meutralize with cross-coupled capacitors when both grid and plate are tuned with balanced circuits. This is in effect, a bridge circuit.

In my defense, I suggested a 0.02 fix on a $20. rig.

If you want a 25-year-old military surplus rig to work like a $900 1995 rig, you can do it. But it's going to cost more than $900 if you figure your time as worth more than minimum wage.

A speech processor (properly adjusted) is useful on any rig. There's no telling what condition the existing audio shaping circuitry is in on a surplus rig that's old enough to vote. Getting the deviation down to where the rig can be heard and understood on the air is the first step. Better receiver filtering is esssential as well -- but you can buy a superior one-chip FM receiver from Moto for $3. Do you want to go through a varnish-laden IF chain to get a couple more dB when you can go to Radio Shack and buy 20 dB and a hamburger for $5?

I am a strong proponent of CHEAP test lash-ups that provide a go/no-go initial test on surplus gear. It saddens me when people spend hundreds of dollars testing and tweaking a tin-can radio when they could have put a nickel bandaid on it, had some fun, and put the money toward a nice rig -- either a modern rig or a classic that's worth the time and money.

BTW, is there any place in the country where there's enough 6 meter traffic for adjacent-channel rejection to be a factor?

; can I get them from - preferably in the UK, but a foreign source will do,
; if I cant get them here.
;
; The circuit specifies a lead length (1/4") to use on these caps to resonate at
; 144MHz, so substituting any old 500V, 500pF silver-mica cap may not be wise.
;
; davek G8WRB.
```

As I recall (he said in a geezerly voice), the DM15 was one of the rectangular jobs with the dots for color code. There were several sizes of the things, and I suppose but don't know that the DM15 was one specific size. Haven't seen one in a coon's age, and would be surprised if you could still buy one.

Should be pretty easy to set up a test fixture with an HT and diode detector to test for resonance. I'd guess you'd end up with leads just a bit longer than 1/4" on a more modern, physically smaller capacitor if 1/4" was right with the DM15.

A DM-15 is a Dipped Mica (size 15); they use printed value numbers
(eg NNX: NN first two digits, X number of zeros).

Jameco, Circuit Specialists and many others still sell them.

4084. PIC Programmers starting at only $29!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-06 00:00:00 UTC
From: itutec@aol.com
Message-ID: <42kqm3$1tc@newsbf02.news.aol.com>
Source record: 110743

ITU Technologies is proud to introduce the ITU PIC Programmer Model PIC-1, the first truly low-cost and versatile programmer for the Microchip Family of PIC microcontrollers. This programmer is designed for programming Microchip's popular PIC16C6x/7x/8x family of microcontrollers. The programmer is approximately 3.3" x 3.7" in size and features a built-in 18 pin DIP socket and an expansion header. The expansion header is provided for programming adapters and in-system programming of EEPROM-based PICs. A variety of adapters will also be available to support 28/40 pin DIP PICs and other packaging forms. The PIC-1 programmer comes complete with an interfacing cable to connect to your PC parallel port, programming software, and power supply. The included power supply is for US use only, foreign customers must provide their own converter/power supply.

The programming software included is designed to program all of the supported PICs mentioned above. Software updates will be available electronically free of charge. The software allows programming of the PICs program memory, setting of configuration fuses, program verification and the ability to read PIC memory to a file. The software also allows data memory programming, reading of data memory, and bulk erase of EEPROM-based PICs. The software is DOS-based and is Windows95 compatible.

An UNREGISTERED shareware version of Don Lekei's Macro+ Assembler for Microchip PIC Microcontrollers (ASPIC) is included with each programmer for your evaluation.

SPECIAL INTRODUCTORY PRICING FOR INTERNET CUSTOMERS
For a limited time, this special introductory pricing is available:

ITU PIC Programmer (Model PIC-1) KIT $29
This kit includes:
* an easy to follow instruction manual for building your programmer
* a high quality printed circuit board with silkscreen
* all components needed to build the programmer
* PIC Programming Software for IBM PC AT-compatible Computers
* a cable to connect the programmer to a PC's parallel port
* a power supply for the programmer (for US use)
* a User's manual introducing the PIC-1 programmer and software

ITU PIC Programmer (Model PIC-1) Assembled/Tested $49
As above, but assembled and tested.

ALSO AVAILABLE PIC-N-GO PACKAGES:

PIC-N-GO packages are designed for the microcontroller novice. They include the ITU PIC Programmer Model PIC-1, as above, plus a PIC16C84-04/P microcontroller. This EEPROM-based microcontroller is ideal for the novice and the PIC-N-GO packages are the most attractive programmers available for the beginner. You can program and erase the PIC16C84 many times without the use of an EPROM eraser, making it the best choice for those starting out with microcontrollers. These packages are great for students and hobbyists looking to acquaint themselves with microcontrollers.

PIC-N-GO KIT only $39
* includes PIC-1 programmer kit and PIC16C84-04/P microcontroller (w/ data sheet)

PIC-N-GO Assembled/Tested only $59
* includes assembled and tested PIC-1 programmer and PIC16C84-04/P (w/ data sheet)

Quantity discounts are available, making these packages the perfect choice for schools and clubs wishing to teach introductory microcontroller usage.

All products include a 30-day money back guarantee and a 90-day warranty. Due to the nature of kit building, all kits must be returned unassembled to qualify for a full refund.

Please e-mail us at ITUTec@aol.com with your questions or if you would like ordering information. Also, see our World-Wide Web page at http://www.iglou.com/itu for more product information!

As of Jan, 1993 Don Johnson could be reached at:
Box 595
26659 Capay Street
Esparto, CA 95267-0595
Although he is not in the antenna business, he sells a few parts and will
send you a printout of the construction details.
Maybe he has some books left. They have only been out about 2 years.
He doesn't give a phone # in the notes, but refers to phone calls
regarding construction problems. Maybe information gives it out.

4086. Looking for old QST articles

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-06 00:00:00 UTC
From: VE4KLM <slmusr03@MBnet.MB.CA>
Message-ID: <Pine.SUN.3.91.950906152359.23218B-100000@access.mbnet.mb.ca>
Source record: 110745

I am looking for several articles in old QST magazines that are no longer available at any of the local libraries here. Most of the libraries only catalogue articles back to 5 years ago on micro film. After that you are on your own.

If any one can help me, I would like the following articles :

QST Apr 1959, "An inside picture of Directional Wattmeters", W. Bruene

QST Jul 1973, "A simple computing SWR meter", D. Fayman

QST Oct 1956, "The Monimatch", L. McCoy

Ham Radio Aug 1979, "Broadband Power Tracking VSWR Bridge", H. Perras

Ham Radio May 1980, "Automatic VSWR and Power Meter", V. Leenerts

Also, I find that alot of schematics and articles only deal with HF, how about anything regarding VHF VSWR measurments ?

You can fax (if you don't mind) any articles to the following fax number where I work :

204 783 8286

If you can scan the article (GIF or JPG) that would be even better since we have the UNIX version of XV at our disposal.

I hope some one can help me here. Thanks.

Regards from

I'm looking for a book called
"40 years of HF mobileering" by Don Johnson. I have tried
Ham Radio Outlet, Portland Radio Supply, Norvac Electronics,
Powells Technical Books, Old Tyme Radio Company, and The
ARRL. I also tried our County, and State library, no luck.

I am sure that this book is out of print, but since several
people have suggested it as a source of information, I have
reason to believe that it does exist. It is the Radio
equivalent of searching for the Necronomichon (fictitious
book of spells and names of the dead).

Anyone know where I can find a copy? I'm looking in particular
for plans to build a motorized tuneable HF mobile antenna.

Thanks,
Ed Burress

I have an Oak Hills QRP Explorer 80M kit built radio, and am having trouble receiving any signal. My Sony SWL radio gets good signal on 80M-ie W1AW code practice, which I need, but the Explorer is silent. The factory says it is properly aligned (they did it-I don't have the instrumentation) and working. Do I need a true 80M antenna for reception? (inasmuch as I don't right now) Would an antenna tuner help? All replies appreciated-save bandwidth if possible and email to

BUT! It would probably be twice as reliable. Kenwoods and Polaroid cameras are in one way very similar: Cheap to buy, expensive to use. Polaroid film aint cheap, and neither is getting the same radio fixed 3 times for the same problem for $150 - $200 a shot.

Poor to fair performance from both.

Well, lets see what this turns into.

I have a great radio that I just won't unload, at least not yet. It is a Drake B line, all tube. I just haven't been all that satisfied with the reliability (real or perceived) of most of the Jap Crap on the market.

What I have been thinking of is this - I would like to convert some parts of this to solid state. I would like to do this only because of the difficulty in obtaining tubes. The section I was considering doing first was the transmitter. Replacing the driver and final stages at first, then moving back into the earlier stages. The final stage is pretty well defined in my mind. Something like an MRF151/141G in push pull, followed by appropriate low pass filters. I'll probobly run it at 36 Volts('151) or 24 Volts ('141) or thereabouts. The part I can't quite figure out yet, is how to get from the grid (high Z) point of the driver down to 50 ohms, where I could then use some kind of wide band amp of the MHW590 variety. Would a current feedback op amp like a Comlinear device be appropriate here? Any thoughts?

Nope, just a single 4CX250B in lowband & VHF, or a single 4CX35O in the
UHF versions. They were called Power Mates. Don't remember the
combination numbers. Absolutely bullet proof design. I did do a couple of
Motorolas in the beginning, and they were push pull. In the usual
Motorola fashion too, a whole lotta clap-trap, hoses, clamps, and general
doo-doo. Nowhere near as easy to work on as compared to the GE stuff.

>
>

Actually the prefix can be CM or DM. CM is Millitary, and DM is commercial grade. The number is the case size and lead style. The value is either directly printed NNN with the tolerance printed directly or if a tailing tolerance code (D,K, or J) is present the third digit is the multiplier. So a part labeled CM-05ED 150J03 is a Millitary grade 15 pF .1% 500 volt rated device with .120 inch spaced non-crimped leads. The current varies with manufacturer for each case style!

On the other hand a DM-05 150 10% is a 150 pF commercial grade part.

So watch out for the prefix and the letter after the value code. No D,K, or J and you read it direct as the number, 152 10% is a 152 pF, 152Dxx is a 1500 pF.

On a lighter note, I guess they use D for commercial and C for millitary because neither letter has anything to do with the grade type name. ;-) Simple system isn't it?

Wes Stewart <N7WS@azstarnet.com> wrote:
>Screen neutralization is used when the self-neutralization frequency is below the
>desired operating frequency.
Actually, screen neutralization is done when the tube is operated
below the self-neutraliation frequency. For instance, the
4CX500A/4CX1000D has a self neutralization frequency of 140-170 MHz
and the 4CX15000A has a self neutralization frequency of 120-150 MHz.
A lot depends on the socketing. The addition of series inductance in
the screen lead develops the voltage needed for neutralization. And
this inductance can be varied by a variable capacitance in parallel or
in series. As a practical matter it's easy enough to do with variable
inductance by simply adjusting the size. length or number of grounding
straps from screen to ground. Operating the screen at DC ground makes
this easy to execute. "Care and Feeding..." has a good theoretical
discussion no practical examples. If you're interested in a few
references let me know and I'll check my library.

With a typical air-system socket incorporating a screen bypass, you
can do the same by inserting tabs of PTFE sheet between the screen
fingers and the tube ring. Measure the reverse transmission loss from
output to input with the tube on idling bias, and insert tabs until
the loss is maximized.

You can use screen neutralization above or below the
self-neutralization frequency. When you're above you use net series
capacitance to cancel part of the screen lead reactance. When you're
below you add inductance to increase the screen lead reactance. As an
example, the 4CX5000A has a self-neutralization frequency of 150-170
MHz, depending on the socketing. And yet we used it for years as a
screen-neutralized amp. Very stable too. Even given the primitive
internal structure of the tube.

From: richer@cambridge.village.com
Message-ID: <42n7ba$3is@cambridge.village.com>
Source record: 110757

Greetings to the assemblage...

I've a problem not specifically ham-related, but well
within the abilities of those here...I hope...8*)

I've just refitted an ancient Land-Rover with a new alternator
to replace an elderly 20-amp generator. Unfortunately, the
ammeter now pins out (it's a 30-amp meter on a 60-amp
alternator - ungood!)

I'd like to put a shunt resistance behind it to halve the
meter reading, thereby making it at least usable and functional.
My own thought was a small coil of AWG 14 copper wire across the
pins of the meter might help, but I'm not sure of lengths and so on.

Anybody give me a hand here? Old Churchill and I would be most grateful,.

Hey, if it's good enough for NASA, and repeaters, why not?
Can't be worse than some of the noises output by certain
repeater controllers, now orphaned. :-)

To implement a courtesy beep, you need a dual 555 chip. One
section is made to free run for the tone, and the other section
is setup as a one shot to hold up PTT and gate the tone onto
the mic line at the end of a transmission.

Grainger Associates 6710 duplex radio. Rack mount, 15 watts, duplexer included, 24 MHz split. Works good, costs little (surplus anyway). These radios were originally intended to supply the equivalent of a 4-wire leased line over radio in the spectrum immediately above 928 MHz. A crystal change and a bit of tweaking brings them down into the ham band. And a simple controller turns one into a repeater. The harder part is finding mobile and HT rigs for the users.

: Al, We used special materials for accurate shunts at Prime Instruments,
: and cheap ole brass for cheap meters. What I would do is find a 30 amp
: load, and play with a shunt until the meter reads 15 amps. That sho ain't
: accurate, but it's easy. I don't think you want or need a 1% shunt anyway.
: Just be sure the material is wide enough so it doesn't get too hot. That
: will minimize drift.

Good ideas. Some suggestions to get you started: _sometimes_ such meters already have a shunt, located remote to the meter, so the full battery current (usually they monitor all battery current except the starter current, not actually generator current) doesn't have to come to your dashboard. If that's the case, then a shunt placed at the meter will depend on lots of other things like resistance of the wires from the meter to the original shunt, ...

But assuming all the current goes through the meter, if you put a 10 to 15 amp load (e.g. headlamps) on and measure the voltage drop across the meter, then you can figure the resistance you need for the shunt, so you have a starting point. Specifically, to halve the meter scale, shunt it with a resistance equal to the meter resistance, or the measured voltage divided by the indicated current. And if the meter internal resistance is composed of copper wire, then if the shunt is the same temperature as the meter, it would be most accurate to have the shunt of the same material, or at least one with the same temperature coefficient of resistance. In this application, it just isn't going to matter that much anyway... copper or brass should work fine. 14 gauge copper is 2.5 milliohms per foot, and should handle 15 amps with very modest temperature rise. Beware of keeping very solid connections so the current is shared equally between the meter and the shunt!

4103. (HELP)CORE CHOICE FOR COIL DESIGN

Newsgroup: rec.radio.amateur.homebrew

From: uid@ornl.gov
Message-ID: <uid.45.304F47BC@ornl.gov>
Source record: 110762

I am working on a radio design for thru the ground radio using coils as the receiver and transmitter antenna.

I need a impedance matching transformer between the coil and the receiver. The problem is that I need a very high al value (Large amount of inductance).

Powder Iron toroids are out of the question because of size. My other choice is a ferrite pot core made by Amidon which is type material 77. It is of the right size and will accommadate the windings. This material is primarally used at higher frequencies than the 31 KHZ I wish to use.

Will this type of core material (type 77) cause excessive core loss (poor sensitivity due to core loss at receiver impedance match) at the frequency I wish to use on receive (31KHZ).

If so, Then can you suggest another core manufactor and type material.

>of the difficulty in obtaining tubes.

IMHO, you're going about this the wrong way, and for the wrong reasons. Tubes aren't that hard to find, so if that's all you're after, there's no reason to do all that work. OTOH, there *are* legitimate reasons to convert to SS. Better frequency stability, better receiver specifications (if converted properly), higher efficiency (no filaments), less heat, etc.

I personally always thought the real trouble with tubes was the way their specs fall off with age. If it was me, I'd start with the RF amp & mixer, then the VFO, then work my way through the IF to the audio. The TX driver and finals would be the last to go.

That will allow you to power the rig in the interim with the addition of only a small 12V supply. Converting the finals first, you end up having to use *both* a large, high current LV supply and the large HV supply that came with the rig.

I also think that a conversion in this way provides the most bang for the buck. Receiver specs and frequency stability can be greatly improved at relatively low cost, meanwhile, the tube driver and finals continue to put out a signal every bit as good as anything on the market. :)

: I teach a communications class for graduate students in management curriculums
: here at NPS. I require a class project and one of the options is for the
: students to get a no code tech license and build a kit. Many of the students
: (who have never seen a resistor, etc.) choose to build Ramsey kits and over
: the past three years I have seen about 50 FM stereo transmitters and 2m and 6m
: transmitters and receivers. The students have always been able to get them to
: work and their complaints, if any, are that there is a part or two missing
: (Ramsey always sends the missing parts), and that they had trouble determining
: what some of the componets were (I have had students ask how to tell which
: lead is which on resistors, etc.).

: Thus it is my opinion that anyone could build any of the Ramsey kits and
: that they will work. The smarter and more experienced one is, the more
: likely you are to want to modify and improve the kit, but they all seem to
: work as specified.

Of course, the problem with Ramsey kits is that while they may work, they
typically don't work well for what you pay. For the cost of the QRP HF
transmitters, for example, you can purchase a copy of "QRP Classics" and
a few parts, and build several better-performing rigs, for less money.

Ramsey is also known for having problems with spurs and harmonics
with their transmitters, so much so that they can be illegal. A recent
magazine review of their 2M transciever kit noted that when the kit
was assembled and aligned according to the manual, it failed to meet
FCC regulations for signal purity. Since the average Ramsey purchaser
is unlikely to have access to a spectrum analyzer, the user could be
in for a nasty surprise.

Are there any files or programs for the Macintosh, ie. is this a PC/Mac compatible cd-rom?

I use a Power-Mac and have Softwindows to run Dos and windows software, but I prefer native software for the speed and ease of use. Can I use your product with my system?

-I'd like to use mine for a 28mhz tunable if for a DEM 432 mhz IF
transverter.
-
-Thanks,
-Joe - AA3GN

You can go to your "friendly" neighborhood Radio Shack store and
ask for a Service Manual for your HTX-100. They cost around $15.
This is the book that is used by the service technician.
I think you can also call 1-800-THE-SHACK and order it on your
credit card. It won't have anything about modifications but it has
a detailed schematic. As far as the low level transmit you might
be able to modify the output section for low level output.
I guess you are looking for the milliwatt range. It might be easier
to build a 30db attenuator.

Al, We used special materials for accurate shunts at Prime Instruments,
and cheap ole brass for cheap meters. What I would do is find a 30 amp
load, and play with a shunt until the meter reads 15 amps. That sho ain't
accurate, but it's easy. I don't think you want or need a 1% shunt anyway.
Just be sure the material is wide enough so it doesn't get too hot. That
will minimize drift.

I notice you haven't had any replies here on the newsgroup, so I'll give it a shot. The metering technique you're describing sounds like the Monimatch design published in old (60's) editions of the ARRL Handbook. One of the problems with that design is that it's frequency sensitive. I think you would have a great deal of trouble making it work well on both HF and VHF.

I know this won't help you build a meter, but maybe it will save you the trouble of building a bad one.

>
> Roger

Here's a repost of the Z1A mods:

Ok, after messing around with the radio on my own and then getting the
"official" mod, here's a summary of the various diode mods for the Z1A:

Icom Z1A mods

[B]+[#]+[POWER] = Extended Receive.
VFO *DISPLAYS* 50-299.900 and 300-999.900.
AM Aircraft band enabled.
SET mode now has a new "PLACE" function for setting
the direct entry starting digit.

There is room for four diodes in the Z1A located on the CPU board to the left
of the ribbon cable connector. On a US version, only the bottom two are
installed. D15 is just below and to the right of the four diodes. These
diodes are bigger than the rest of the surface mounted components and are easy
to spot.
The official ICOM mod (which I unofficially saw...) is to remove D15 for
extended TX and to use the above keyboard mod for extended receive. According
to the sheet, the 800-900 band is NOT available in US versions.

```
+-+ +-+
| | | | <---- Installing diodes in either of these seems to do
+-+ +-+ nothing.
```

```
+-+ +-+
| | | | <---- IN: US Version 144-148 TX 440-450 TX
+-+ +-+ OUT: Extended 136-174 TX 380-470 TX (Lose auto-repeater
^ and tone encode)
|
+------------ IN: US 144-148 TX 440-450 TX
OUT: European 144-148 TX 430-440 TX
```

```
+-+
"D15"--> | | <---- IN: US Version Stock
+-+ OUT: Extended TX 136-174 380-470 (keeps auto-repeater
and tone encode)
```

A word of warning about messing with the four diode pads: If you detach either one of the installed diodes, the CPU will reset and you'll lose ALL of your memories. (found that out the hard way...) D15 doesn't seem to affect the memories at all.

Since the 800MHz band is not available in US versions, my guess is that there's a keyboard mod to unlock it instead of a diode. The diodes only seem to control the country versions. If anyone has any more keyboard mods, please post them.

You're right! Hard, but not impossible. I guess I have reccolections of reading and hearing about the lack of availability of the 6JB6's for the final. Heard some of the boys on 3898 and thereabouts talking about this a while back.

>I personally always thought the real trouble with tubes was the way
>their specs fall off with age. If it was me, I'd start with the RF
>amp & mixer, then the VFO, then work my way through the IF to the
>audio. The TX driver and finals would be the last to go.

After writing the message, I re-thougt that myself. The vfo is already solid state, it's a J-FET if I recall. I guess the real hard part woud be the stage that mixes the vfo with the xtal lo. Re-doing that stage would be a challange!

>of only a small 12V supply.

There is a 4 pin socket that has 6.3VAC on it. This I believe was there to power some outboard vhf converters. this could be doubled,filtered and regulated to provide DC for the solid state stuff. Shoud be plenty of extra capacity there.

>improved at relatively low cost, meanwhile, the tube driver and finals

I appreciate the suggestion, but as they say, "been there, done that". The board assembly from Sears is around $85. I went up the chain of Sears technicians and reached the end. The answer was basically (as expected) that the discreet chip is not available through Sears, only the board.

I've also received a couple of replies that indicated this chip cannot be cross-referenced nor does it show up in any semiconductor database. I'm coming to the conclusion that the board is now good for parts (less one).

Thanks to all for the input.

Hi Fred,

You are of course correct that screen neutralization can be done both above and below the self-neutralizing frequency. I was replying to the post that discussed the melt-down of the resonating capacitors, so I assumed the case of operation at the higher frequency.

"Care and Feeding" does suggest, however, that below the self-neutralizing frequency, normal cross-neutralizing circuits apply. (para 5.6.1) It mentions the series capacitor method for use above the self-neutralizing frequency in paragraph 5.6.2. It goes on to say that if the tube is to be used over a wide range of frequencies, then the capacitor should be user adjustable. This reinforces my suggestion that this is a narrow-band solution. All of the above is in the case of tetrodes and pentodes, which I believe was the subject of the discussion.

Personally, I'm sticking to my 8877s :-)

Thanks for clarifying my "shoot-from-the-hip" response to this <g>.

Several of these were also in older versions of the ARRL HAndbook so if your library has them you might check. All radio magizines ever published are available from Carnagie Mellon University Library in Pisttsburg, Pa. I've been there and seen most of them. They will furnish copies on reguest thru the inter library loan system here in the states. Also Maryland Radio Center in Laural MD has a room with most every Hamm magizine ever published. The owner does not do research but if you are in the area its open to the public and had a 10 cent per page copier. One of the local radio clubs take care of it. Its a great idea and more clubs should do something similar.

Yes, sounds like you're trying to ruin a fairly good pair of old
radios by turning them into poor clones of modern Japanese radios.
The Japanese have more experience, and more engineers. You're unlikely
to come up with anything that works as good as the B line does now,
much less as good as a modern Japanese radio.

>in for a nasty surprise.

No lie! Ramsey isn't the only one making potentially dirty kits,
but they are the only ones whose design enables the transmitter
while an out of lock synthesizer sweeps the band. That's an
unforgiveable error (and easily fixed). However, as I said,
Ramsey isn't alone. Much the same could be said of Hamtronics
kits or the late VHF Engineering offerings. Even Ten-Tec decided
to withdraw their transceiver kit because they found they couldn't
design one that an amateur with inadequate test equipment, and
inadequate skills, could reliably be counted upon to tune up to
meet Federal regulations. Rick Campbell's no-tune designs seem as
near foolproof as it gets, but even he can't design damn-fool-proof
kits.

Folks, if you're going to build transmitters, look at the kit
suppliers as convienent one stop purchasing agents, but know
enough about design and testing to correct their errors and
tune up their designs properly, just as if you were working
from scratch. If all you know is how to follow directions in
a manual, you'll likely end up in deep doo.

>the trouble of building a bad one.

The Monimatch isn't a *bad* SWR meter. The fact that it's frequency sensitive just means it's a bad wideband *power meter*. But since SWR is just a ratio, you don't care whether the forward and reverse readings are absolute or relative. All you need is a CAL pot and a set mark on the meter. There are some practical problems with maintaining directionality over a wide range, but that's typical of most SWR meter designs and not unique to the Monimatch design. It might not be my first choice for addressing this problem, but it wouldn't be my last choice either.

Tom, Actually the way we made sure stray resistance didn't hurt was to tap the meter across an inner section of the shunt material, with the high current connections at the outside. We used low current meters. If the meter is a full current meter with internal shunt (usually the case in cheap automotive or generator type moderate current applications) I can't think of any way to avoid contact resistance problems. Can you?

The local power company was using them to control their network before they switched to fiber. I bought all they had at a surplus sale. They were using GA 6710s as masters, GA Scancom 1200s in the switchyards, and a bunch of Motorola MR9600s for trunks. I've been peddling the excess units at hamfests for a couple of years now. I still have 5 of the MR9600s available, in 8 foot rack mounts. $150 each, you pay truck freight.

Hi Wes and Fred,

Not only does the amp have a restricted operating range, the designer has to exceptionally careful that no spurious resonances occur. The screen grid tuning circuits decrease isolation at other frequencies, and can create problems with out of band stability.

All in all, I prefer conventional bridge or other broad band techniques, and a tube that isn't operated near or above it's self neutralizing frequency.

Yep, I agree. My original post said:

"Screen neutralization is used when the self-neutralization frequency
is below the desired operating frequency. The screen inductance
is series-resonated to ground the screen. Obviously, this is effective
only over a narrow frequency range, which opens up the possibility
of instability at other frequencies. A common problem with the myopic
design method <g>."

Wes

4140. Seeking Info on Short-Range (8-9 ft) RF Data Links

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-09 00:00:00 UTC
From: <>
Message-ID: <42slgb$s9b@news.onramp.net>
Source record: 110799
Cross-posted to: comp.robotics.misc,sci.electronics,rec.radio.amateur.homebrew

Can anyone direct me to an info source for short-range radio links used to keep several robots in constant contact with a central computer, in a constrained environment like a test maze? Must be low-power and light-weight.

I've checked rec.radio.*, rec.radio.amateur.*, sci.electronics; and searched the Web various ways. I've been seeking such for a couple of years. It seems there are several FM transmitter ICs for Mr. Microphone/Karoke toys, not too many simplified FM receiver chips and no one I've found that builds an FSK modem into them. It seems this problem crosses multiple disciplines so I've been unsure of the best place to look.

I'm looking for a very low-cost approach to have a 9600-baud serial link between non-line-of-sight but close-proximity points. It seems such gadgets would be useful for many different projects; radio-controlled cars, radio-mice, robots etc.

Originally I considered ultrasonics, which I don't think would be as reliable for data transmission and just seems messy. I'm also thinking of pulsed, dispersed IR with many detectors mounted around the maze. I need bi-directional, so the maze would also have many ganged transmitters with a receiver on the robots.

I'm looking for something I can build rather than buy. This is a pet project of mine for several years and I've been hoping the technology would catch up and I would find a two-chip solution that you just add a few discrete components to and go.

Have I overlooked an easy solution here? Any help is greatly appreciated!

>>
The output of an op amp is a very low-impedance voltage source. When one tries to drive a capacitor with such a source, the op amp has to supply a large amount of current to charge and discharge the capacitor during each part of the AC cycle. The higher the frequency, the more the current. And when the capacitor gets charged, what have you accomplished? The voltage it's charged up to is just what you would have had anyway without it in the circuit.

The various IC manufacturer's books all say if you NEED a capacitor on the output of an op amp, at least put a small value resistor in series with it -- typically 10-50 ohms or so, depending on the application. Without the resistor, the current drawn by the op amp will be needlessly high, and due to excessive phase shift it may become unstable enough to actually break into oscillation.

What I have is an old KRACO cb. It is called "OUT-A-SIGHT" and the model # is KCB-4060. This is an under the seat / in trunk type of radio, with channel selection, volume control, and squelch controls in the mic, with a long cord connecting the mic to the radio. It's really well built built unit! Shielding, all metal housing, feedthru caps, well done. Oh, it works too.

What I would like to do is find a schematic for this radio to determine if it is possible (I'm sure it is) and just how hard this would be to convert 10M. I does have a PLL type synthesizer in it's own sheilded box. I does NOT look anything even remotely like the HY-GAIN type of radios that I'm familiar with. Being frugal, (or is that cheap?) I hesitate to buy a Sams photofact for it. It would be worth more than the radio.

Does anybody out there have a schematic / photofact for this unit? If so, please let me know. I'll be happy to pay copying costs, postage, etc.....

Pat Tracy, KE1C

In the 8 - 9 foot range you will find that infrared communications is far superior. It is a simple matter to use commonly available IR detectors (they cost around $2.50) and LEDs to transmit serial data. With checksums and an ACK NAK protocol this can be very reliable and really inexpensive.

I am having a hard time myself looking for SSB filters at 9.0 Mhz .

Incidentally, it may be possible to make simple 4 crystal 10 mHZ filters
usingh 4 crystals and 4 capacitors + 2 transformers, but the performance
will be not in the
same league as a professional 9.0 Mhz 10 crystal filters .
I ts hould be fine for CW or rough SSB though.

Well, I for one remember 807's. Had a couple last night.

I also have a real 807 on a shelf above my Pentium to remind me where
this all started. :-)

For simple commands that only go across the link in small bursts, Holtek makes some nice chips for remote control applications These chips can be used to modulate IR, RF or whatever. They just encode/decode a ternary (3 state) string which you program by tying a few inputs high or low, or leaving them open. I've heard the open state can be unreliable, but I would think that tying it to a voltage divider made from two equal value resistors might keep it stable. Untied high-impedance inputs have a tendency to float around with 60Hz current in your walls.

For a continuous link, the XR-2206 and XR-2211 can be used to do simple FSK encoding and decoding. The chips are made by Exar, but can also be found from other suppliers. However, they only work up to a few 100 kHz. You could chopper-modulate them up to the frequency of interest, though, and then filter it to the proper bandwidth. Then, just chpper modulate it back down before demodulating it at the receiver.

Of course, you would have to abide by the good ol' FCC part 15, no matter what you do, and the 26.96MHz to 27.28MHz and 49.82MHz to 49.90MHz bands (I think those frequencies are right, but I'd check that) are commonly used for remote control applications (like RC cars and boats, etc.). For FSK at these frequencies, you might try a 74HC4046 (or 74HCT4046) made by RCA/Harris. (Other versions of the 4046 like the original CMOS CD4046 made by Harris, or the MC14046 by Motorola) only go to around 1 MHz.) It might be tweaked into working at the 27 MHz band with a really small cap. However, it may be unstable. Also, you could build a voltage controlled oscillator with a varactor cap and a transistor and a crystal to control the frequency

and use that for generating FSK. Crystals for such a VCXO are available from hobby shops who sell remote control items. There are also several PLL circuits which will operate at those frequencies.

The chip in most of those Mr. Microphone toys is probably the BA1404 made by ROHM in San Diego. It doesn't even operate over the entire FM broadcast band if I remember correctly (just the lower half, I think), but might be made to work at lower frequencies. You can buy a kit based on the BA1404 from Ramsey Electronics. Also, they have an FM receiver kit. You could start with these kits and modify them to transmit data.

I think there are many ways of doing this with the current technology, but all will require some tailoring to the specific band you are planning to transmit in. That usually means doing a little math to calculate tank frequencies, filter cut-off frequencies, RC time constants, etc. All are pretty cheap, too. Good luck!

-Rob

4150. WTD: Source for Surplus Inductors, Transformers, Etc.

Newsgroup: rec.radio.amateur.homebrew

I am working on a homebrew project, and need a reliable source for
SURPLUS hard to find and obsolete power transformers, coils, and other radio
parts. Your help is appreciated. Also, please see the following list of
parts I need, maybe we could work something out.

Thanks,

Robert/KJ7BO
rmwatson@eskimo.com

LIST:

TRANSFORMERS:

Triad R-8A (or equivalent)
250-0-250 volts, 75ma
5v, 2A
6.3v, 2.5A
(Qty: 1)

Stancor PM-8410 (or equivalent)
360-0-360 volts, 120ma
5v, 3A
6.3v, 3.5A
(Qty: 1)

Stancor A-3823 (or equivalent)
8.5K Ohm to 3.2 Ohm voice coil
(Qty: 1)

Miller 512-W1 (or equivalent)
1,500 KHz/(Kc) Converter
(Qty: 1)

CHOKES:

Thordarson 20C50 (or equivalent)
350h, af-coupling
(Qty: 1)

Thordarson 20C53 (or equivalent)
12h, 80ma filter
(Qty: 1)

National R-100 (or equivalent)
2.5mh RFC
(Qty: 3)

Stancor C1001 (or equivalent)
10.5h, 110ma
(Qty: 1)

Stancor C2305 (or equivalent)
5h, 100ma
(Qty: 1)

COILS:

Barker & Williamson 40JEL (Plug-in end link set)
Barker & Williamson 80JEL (Plug-in end link set)
(Qty: 1 each)

Note: If anybody has suggestions on where to learn how to make the above coils, please let me know, ie books, or whatever.

Your help is indeed appreciated, and I will provide an update as to what has been found, etc.

For sale posts belong in rec.radio.swap only. That is the charter of
the newsgroup. Buying, selling, and trading posts do NOT belong in any
other newsgroup in the rec.radio.amateur hierarchy.

This is all explained very nicely in the "Guide to the Personal Radio
Newsgroups," that Jay Maynard posts on the 15th of every month. One
begins to think maybe it should be posted daily. 8^{)

JUST A HAM RADIO TERMINOLOGY CLARIFICATION: TELEPHONE INTERFACES TO
RIGS HAVE HISTORICALLY ALWAYS BEEN CALLED A "PHONE PATCH", NOT A "PHONE TAP".

"TAPPING" OF TELEPHONES HAS OFTEN BEEN DONE WITH A LINEMAN'S HANDSET,
CALLED A "BUTT-IN", WHICH CLIPS DIRECTLY ONTO THE LINE PAIR.

A TELEPHONE INTERFACE OR "PHONE PATCH" FOR A HAM RIG IS BEST DONE WITH A
TRANSFORMER -BASED HYBRID, WHICH IS EASILY HOMEBREWED. DESIGNS FOR THESE HAVE
BEEN AROUND SINCE THE 50'S IN NUMEROUS HAM RADIO ARTICLES, INCLUDING QST.

>Uh... no, read the article... he means phone tap. autopatch (where one
>can make phone calls from a HT) is something different..

No, he's correct. Phone taps are what the FBI, spies, and other
scum do, broadcasters do phone interfaces, or patches, and so do
hams. A phone patch is a *two* way interface with the phone network
while a tap is a one way eavesdropping technique. You're thinking of
autopatching, which is a semi-automatic variation of phone patching
used by repeater stations. Phone patches pre-date repeaters and HTs,
and have traditionally been manually controlled by the local operator.

Patching terminology came from the broadcasting world where phone
lines are traditionally terminated in patch fields through two wire
to four wire hybrids, and the operator could patch the line into the
console at need. Prior to the Carterphone decision, the telco had
to supply the hybrid. Now, of course, we can supply our own.

The local power company was using them to control their network before
they switched to fiber. I bought all they had at a surplus sale. They
were using GA 6710s as masters, GA Scancom 1200s in the switchyards,
and a bunch of Motorola MR9600s for trunks. I've been peddling the
excess units at hamfests for a couple of years now. I still have 5
of the MR9600s available, in 8 foot rack mounts. $150 each, you pay
truck freight.

Hi Wes and Fred,

Not only does the amp have a restricted operating range, the designer has
to exceptionally careful that no spurious resonances occur. The screen
grid tuning circuits decrease isolation at other frequencies, and can
create problems with out of band stability.

All in all, I prefer conventional bridge or other broad band techniques,
and a tube that isn't operated near or above it's self neutralizing
frequency.

> I'm also thinking of pulsed, dispersed IR
>with many detectors mounted around the maze. I need bi-directional, so the
>maze would also have many ganged transmitters with a receiver on the robots.

IR is probably your best bet. I've seen point-to-point links over 1/4 mile
using IR... no licensing hassles, no interference from CBs or baby monitors,
etc.

By sheer coincidence, the October MacUser has a quick review of an
IR-based LocalTalk setup called GameNet. It's not cheap ($160 for a
pair, includes a two-person copy of Marathon), but it'll give you lots
more than 9600-baud and covers a room up to 25'x25'.

Given that your robots probably don't have Macs on board, this isn't
exactly what you're looking for... but the technology *IS* available at
the consumer level. You probably won't even need to mount detectors;
just paint the ceiling white & aim your transcivers straight up.

The company is Photonics, SanJose CA. 800-997-2326 or 408-955-7930.
Not that they're going to send you a schematic or anything, but you
might be able to get some leads on where to find the IR gadgets....

Hope this helps.

I just purchased a shiny, new-looking Heath HX-1681 at an auction, cheap. It is a transmitter for 80 through 10. The final has a pair of tubes - looked like 6146's but could be sweep tubes. I didn't open it up that far. Can anyone tell me a bit more about it? specfications? vintage? I'd also be interested in locating a schematic and/or manual for a fair price. It's also missing the power cable, an 11 pin "octal type", male on one end, female on the other. (I don't know what else to call it, it looks like an octal tube base, but with 11 pins.)

Geez Gary, you're making a lot of assumptions about Pat's technical ability aren't you? Most tube designs aren't that difficult to substitute with solid state, as long as the overall plan for devices and circuits is laid out from the beginning.

You know, as a fun project, this is sure a lot easier than starting from scratch. So what if the intrinsic value of the equipment is lost? These rigs aren't exactly rare, and besides, he didn't say he wanted to sell it when he was done.

Personally, I've always considered projects like the one he's describing to be an integral part of homebrew. Based on past modification articles in Amateur Radio magazines, I'd say other Hams do too.

It's a fairly good CW only transmitter. I got mine about 15 years ago.
I built the xmtr and my wife built the power supply for me. It DOES
need an external power supply. It uses 6146 tubes, and a tube driver
for the output stage. I've had trouble with the driver tube going
bad at a fairly regular interval. I can bring in the manual and
send you the specs, if you want.

Neutralization is not necessary if adequate output to input isolation is achieved, approximately 10 to 15 dB greater than the desired stage gain. Since triode have less gain, they are more tolerant of sloppy physical/electrical design.

ARRL Handbooks 1986 through 1989, maybe others, but I have those two years, cover a 4CX1000A/1500B grounded tetrode 2 meter amp requiring only 10 watts for 1500 watts output. Central to the design is physical isolation, *and* using a grounded screen rather than a bypassed screen for isolation within the tube itself. They measured the reverse isolation to be greater than 40 dB at 144 Mhz. No neutralization was necessary. The techniques are described.

There was also a 6 meter amp using the same tube but with a screen bypass socket rather than a grounded screen. It too required no neutralization.

Physically, the idea of a push-pull design would be daunting.

One is also tempted to ask: if a single tube can provide the legal limit at or exceeding 400 Mhz, what are you doing with two?

Sure, I remember tubesters, but I also remember that they offered
a lower intercept than the tubes that they replaced. To improve
on the radio's performance, you'd essentially have to redesign
it completely so as to be optimized to work with solid state
devices. That's a formidable challenge, and about all you'd have
left of the original when you were done is the case. If you want
to design and build a high performance transceiver, that's great,
I say go for it, but I don't think the way to do it is to try to
kludge a tube design to work solid state. You can make it *work*,
but I sincerely doubt the performance would be better.

>You know, as a fun project, this is sure a lot easier than starting
>from scratch. So what if the intrinsic value of the equipment is
>lost? These rigs aren't exactly rare, and besides, he didn't say he
>wanted to sell it when he was done.

Well, I agree that "collector value" isn't something I ever consider.
Drill the hole is my motto. But still, to get superior performance
you're talking about gutting and rebuilding. *I* think it's easier
to start with a clean sheet of paper than do that. Then you could
have a high intercept push-pull first stage, a DBM mixer, a termination
insensitive post amp, etc. That's a *major* rework. Now there are some
worthwhile modifications to the Drake line, primarily to the audio stages,
that would be worth doing, and there are better tubes that can be used
in the existing RF circuits, but I don't see converting the PA and RF
front end to solid state as a viable modification project. It's a full
redesign that's likely harder than starting over from scratch.

>Personally, I've always considered projects like the one he's
>describing to be an integral part of homebrew. Based on past

>modification articles in Amateur Radio magazines, I'd say other Hams
>do too.

I agree that *mods* can be good, but what he was talking about doing
goes far beyond a reasonable mod.

TB> Th.Bohl@cern.ch

Thomas, KD4QDM is probably correct since Avantek makes a lot of GaAs FET's for different companies. If you check around you should be able to find an agent for them in France and if you contact them with the numbers from the part they should be able to match it up.

If this doesn't work please post the numbers on this echo and somebody may recognize them, also I can then check my Avantek book to check for a match.

Roy DM stands for dipped mica and the 15 stands for the voltage range.
These capitors are primarily used in oscilators and high freq. amps because
of their stability with temp. changes.

The DM15 is a modern cap and with the specified lead length they are probably
using it to make a series resonate circuit buy using the inductance of the
lead length.

Sorry, That's absolutely incorrect.

CM is millitary grade. DM is commercial grade. 15 is the case and lead style. Didn't my earlier post make it on?

The number following the DM or CM-xx is not necessairly the value with the last digit a multiplier. Let me post it one last time...

DM15 500 5% 500v is a commercial grade 500 pF 5% 500v part

CM10 would tell you it is the same physical size millitary grade part but with crimped leads. And it could be followed with a 500J03. In this instance it is a 50 PF (not 500) 5% -55 to 125 degree c, vibration grade tested between 10 and 2000 hZ.

If the three number value is followed by a tolerence code of D,K,J,G,F, or E the last digit is the multiplier. If it is NOT followed by one of those tolerance code letters the value is as printed. SO a cap marked 151 5% is a 151 pF. A cap marked 151G03 is a 150 pF.

The case size has NOTHING to do with any standard industry wide voltage or current rating.

There are more code letters also, but I think I've made the important points.

To Ham Homebrew Recipients:

I am putting this information on here for any interested parties in building coherent CW equipment. I have a library in progress, currently consisting of about 200+ pages of information on building coherent CW items, schematics, etc. It will eventually contain over 400 pages of data. Most of the items are not spell checked or proof read as yet. I am looking other interested persons who would help in doing spell checks, grammatixs or callsign & name verification. Also the info is there for any interested parties to access.

The location of the library is Anonymous FTP at:
ftp.clark.net/pub/mcclun

You may leave me mail ONLY at mcclun@clark.net not via the .edu account. Those who are interested please take a look and let me know.

4189. TIPS for Kraco CB to 10M Conversion

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-12 00:00:00 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.810918748@eagle.csl.uiuc.edu>
Source record: 110698

Someone ask about a schematic for a Kraco 4060 CB-unit. I don't have info on
that model, but I have some notes on Kraco KCB-4020 (AM 40-chan), and KCB-2320B
(AM 23-chan). Both use the same PLL-02A IC in the synthesizer system..... i.e.
divide-by-n (1 to 512). Exactly the same theory applies as was mentioned in the
earlier post (EASY CB-to 10M SSB). The same 10.695 MHz I.F. frequency is used..
the main difference is that the Midland used a reference of 40.210 MHz, while
the Kraco's use 40.960 MHz to down-mix the VCO frequency to the 2 or 3 MHz
range, suitable for div-by-n (512 to 1) to reach the phase-det ref of 10 KHz.
Again, on the PLL-02A, pins 7 thru 15 (activated when HI) yield divide-by:
512,256,128,64,32,16,8,2,1 in the same respective order. Dividing factor is
the sum of all the pin-values which are held HI (+5v).
The 23-chan Kraco only switches 5 lines. The 40-chan Kraco switches 7 lines,
while the Midland 40-chan switches 6 lines.
Incidentally, if you have schematics, you may not see those higher (40.210 or
40.960) indicated...they get their final "doubling" covertly in the VCO-Mixer
I.C. The 40.960 is four-times the 10.240 MHz Xtal, which conveniently mixes
with the upper I.F. freq of 10.695, to yield 455 KHz which is the 2nd I.F.
(used on RECEIVE ONLY). If you want to review the theory that was posted in
the earlier "EASY CB-to-10M SSB" post, I can E-mail you the files:

I'm probably OK in tech ability department. What I lack is endless hours,
and un interrupted weekends, nights, etc....

>substitute with solid state, as long as the overall plan for devices
>and circuits is laid out from the beginning.

My simplistic approach to designing the receivers (when I get the chance)
where I work is to start with a simple block diagram with gain / loss
numbers, power levels of noise in a given bandwidth and carrier levels at
each stage. I usally do the stages following the LN2 cooled optical
detector pre-amp. My part is making sure that the gain distribution looks
right, none of the mixers, limiters, or detectors are getting crunched at
high C/N ratios, and still have the discriminator be noise limited at low
C/N ratios, etc... These particular receivers don't have to deal with a
large dynamic range, only 60 dB max. Our particular application requires
very good C/N detector accuracy, and very low distortion FM detectors of
different bandwidths. RARELY use an AGC circuit. This is probably easier
that figuring out what stage gains are in the old 'B line.

>So what if the intrinsic value of the equipment is
>lost? These rigs aren't exactly rare, and besides, he didn't say he
>wanted to sell it when he was done.

I side with you on this point. The radio is a 1972 or so radio. All
things considered, I don't put a real high dollar value on it. Sell it?
I guess I'd sell anything if the price was right. Amost anything.

>Personally, I've always considered projects like the one he's
>describing to be an integral part of homebrew.

Gary and several others have pointed out that modifactions such as these,
and my particular approach is somewhat bass - acwards. Lower level,
oscillator, front end or mixer stages should be approached first. This is
good advice. If 6JB6 tubes ever become really extinct, and I don't know
that they're not now, then would be the time to solid state the final.
After re-thinking, I actually would hesitate to dig in and screw up what I
have now. If I should ever find another B-line at a good price (real
cheap or free) that is broken or in poor condition, I'd do that one first.
But for now, I think I'll stick to the first 37 projects on the list,
then, when one of them gets almost done, I'll dig into the B line.

Pat, KE1C

4195. Looking for PIN diode switching info

Newsgroup: rec.radio.amateur.homebrew

4199. Radio for 9600 baud@UHF

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-12 00:00:00 UTC
From: pbutlalj@ia.net
Message-ID: <4332ef$m0j@hera.ia.net>
Source record: 110708
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

Hello Everyone,

I was wondering if there are any suggestions out there for which radios are easiest to convert to UHF 9600 baud packet radios. There are several people in the area that would like to get on the air and it has been a while since anyone purchased any commercial radios that got converted to this mode. Of course we are looking at inexpensive and reliable radios.

Thanks for any information that would be available out there.

Where did you get that info from??
I have the EIMAC book in front of me and this tube is rated
for a maximum frequenzy of 110 Mhz at the max output.
Above that this tube has to be serverly derated and whoever
wants to run it will have quite a time with exessive heating
on 2m. The rated output power up to 110Mhz in class AB
RF linear amplifier is 1100 watts.
reference: EIMAC power grid tubes reference cataloge 489.
The only tube of this type to reach 450 Mhz is the 4cx1500BC
with coaxial socket.But even this tube has only a usefull power output
of 1100 watts .

Greetings, Robert, from a dry and cool Diepenbeek in N.E. Belgium!

I've just this last week had the 'Official 1934 Short Wave Manual' reprinted by Lindsay Publications, tel. 815/935-5353 (before 2pm central time) fax 815/935-5477. It's brilliant, and I think you'd appreciate their catalogue. That particular book is cat no. 4643 $15-95 and worth every penny. Don't know the shipping cost in the US, but Lindsay's service is first rate - I faxed my order with Visa number, and in four days INCLUSIVE the parcel was here in Belgium. Now that's service. They do books (old titles reprinted) on crystal sets, valve sets, Tesla stuff and a pile more. If you want to re-create radios from the 20s and 30s, Lindsay is the place to go.

Snail mail:

Lindsay Publications Inc.,
PO Box 538,
Bradley,

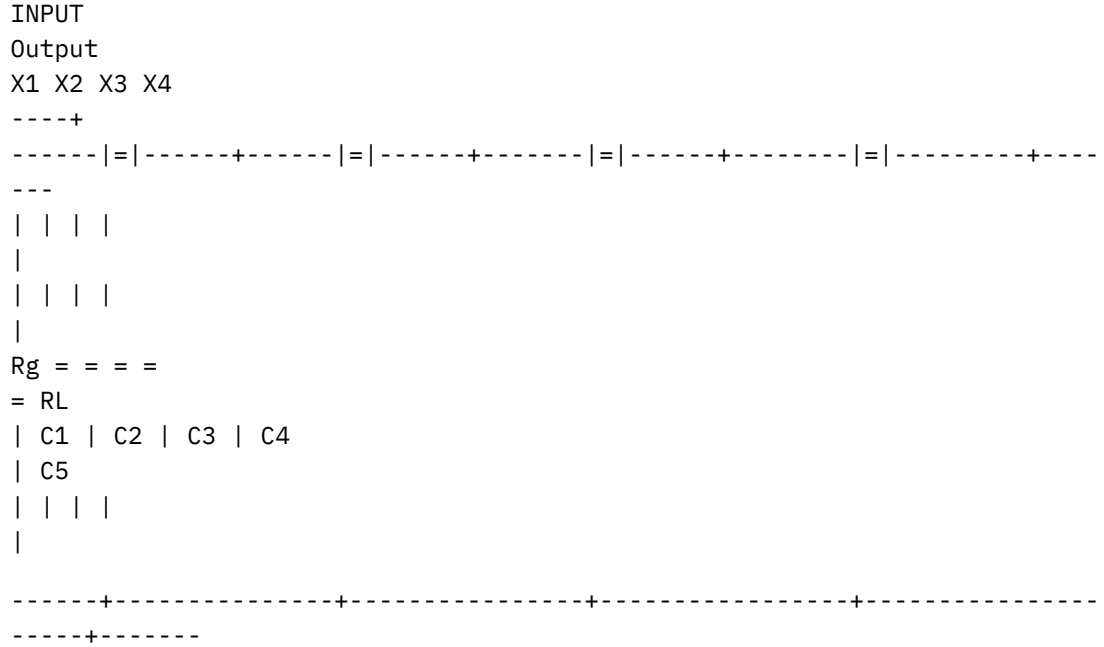
4205. Homemade crystal filters for SSB ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-13 00:00:00 UTC
From: pskh@aol.com
Message-ID: <43828v$4at@newsbf02.news.aol.com>
Source record: 110627

Has anybody practical experience with home made 4 crystal ladder filters
for SSB ? This is what I am talking about:-



Let us assume the following :-

X1 to X4 are typical microprocessor crystals with a series resonant freq
of 8 Mhz
that have been matched to with 200 Hz of resonant freq

C1 to C5 are 100 pf each.

(I am fully willing to try different capacitor values, which will
probably change the
coupling and thus the filter bandwidths .)

My question is , is it possible to get a fairly decent SSB performace
from the above filter ?

Numerically
shape factor of better than 1:2.4
BW of around 2 .5 khz + - 400 hz
stopband attenuation of 40 to 50 db
passband attenuation of < 6 db or so

Qualitatively, Is it going to an usable and pratical SBB filter or is it
just another useless circuit used to clutter the radio handbooks etc.

I would appreciate any thoughts on the above

cheers

The 1994 ARRL Handbook describes a 4mbit link that uses Gunn diode microwave tranceiver. An ethernet card is used as the modem; the device plugs into the 15-pin media access connector. If anyone out there has more information on this, please post it. I'm very interested myself.

Victor,

I can give you the address of a place that sells equipment very cheap.
Write to my friend Bill English at Equipment Authorizations, Box 429,
Columbia, MD. 21045.

Be sure to put attn Bill English on the envelope, and enclose an SASE.
Just tell him what you want to do and that you are looking for some cheap
surplus equipment. They work out of a post office but you can trust them.
Their company has been dealing with radios for 60 or 70 years now. He'll
either handle your request or put you in contact with someone that can
take care of you.

Tom

>
>Can anyone help me out?

A turnstile is a simple antenna, just two crossed dipoles mounted
a quarterwave above a groundplane (usually made from window screen
wire stretched on a frame). Two 1/4-wave sections of 75 ohm coax,
one to each dipole and joined by a coax Tee to a 50 ohm cable to the
receiver is how you feed it.

There are much better antennas. The popular eggbeater style is
better, a Lindenblad or a quadrafilar helix are better still
while still being omni-directional (and circularly polarized).
Steerable yagis are better yet. Cost and complexity rise with
performance, however, and the turnstile is one of the cheapest
and easiest antennas that will offer improvement over the scanner's
whip.

(All these antennas are described in "The Satellite Experimenter's
Handbook, available from the ARRL.)

For passes below 30 degrees above your local horizon, however,
a gain vertical antenna will outperform the turnstile. That's
because the turnstile has maximum gain straight up, where you
need it least because the satellite is closest to you at that
time. The vertical offers gain toward the horizon, where you
need it most because the satellite is furtherest from you at
that time.

Using both, and a coax switch to choose between them, is a
viable alternative for a manned receive site, or an automated
site with the coax switch driven by a timer. This type of
antenna arrangement is only suitable for the LEO birds. For
those in higher orbits, you need the extra gain of a steered
yagi or helix. Hand steering is viable in a manned station,
but automatic rotators are needed for an automated setup.

Your scanner's IF filters are too broad for best results,
but should suffice for most of the LEO birds. For the higher
orbit birds, you need a filter response tailored to the

power spectrum of the satellite's signals in order to have a good SNR. And an antenna mounted preamp will be a major boost if you have a long lossy feedline run. The preamp won't be a great help with an omni antenna that has Earth in it's main lobe, however, because the Earth's noise temperature will set a floor to the achievable SNR. An antenna with its main lobe excluding Earth can benefit much more from a low noise preamp.

Gary

4210. Re: 455KHz IF amp ICs: Any Suggestions?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-13 00:00:00 UTC
From: "rocci@netaxs.com" <"Joe Rocci">
Message-ID: <436b1l$f1e@netaxs.com>
Source record: 110632

Just about any modern transistor or IC is going to have frequency response several orders of magnitude greater than 455 KHz.

Not to worry!

Take a hard look at the Motorole MC1350...it will give you just about 50 dB of gain with an untuned input and a single tuned output...very easy to handle, even without UHF construction techniques.

4211. 455KHz IF amp ICs: Any Suggestions?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-13 00:00:00 UTC
From: stevem@w6yx.stanford.edu
Message-ID: <435955$83a@nntp.Stanford.EDU>
Source record: 110709

I am looking for IF amp ICs for use at 455KHz which include gain control for AGC. Looking through the usual data books: Moto, Philips and the like, I have found lots of gain controlled amplifiers but they all have response from DC to daylight. I would rather not have to worry about UHF and microwave construction issues for a circuit at 455KHz!

Any ideas would help. I am looking for about 50dB of gain or so. More than one device is OK.

Thanks

Steve Muther WF6R

This comming Sunday ...

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
September 17th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

>
>Thanks for your response, and thanks to several other people. I'm seeing
>several good responses outlining approaches I had not considered.

A good source for some inexpensive RF is Electronics 123, there number is
818-913-6735. They have a real inexpensive RF transmitter and reciever
boards, they also handle all of Holteks chips.

If anyone has a short range RF transmitter, (1-2ft), I would like to imbed a
coax wire in the ground for a vehicle to track. I have found 50Mhz on foil
shield wire make a good antena but range is to far, (30+ft).

Any help would be appreciated, must be within FCC guidlines.

snip

Steve,

I think you will be hardpressed to find a device with
low bandwidth these days. There would be a rather limited
market for such a device. I have had good luck with MC1590s
at 9 MHz and I don't see a reason to expect otherwise at 455 KHz.
Regardless of the device type, if you are going to have >50 dB
gain in an amplifier, you must be concerned with following
good design and layout practice. This is particularly the case
if you are including crystal or mechanical filtering and expect
to realize the ultimate stopband attenuation these filters can
provide.

Regards,

Wes -- N7WS

I'm trying some new ideas in RFD and need some difficult-to-find
electronics...

selsyn/synchro pair, 60 cycle, 120vac.

sin/cos potentiometers, or sin/cos rom or eprom

A/D and D/A converter ICs, at least 7 lines of binary (128 count)

360deg (no stops) potentiometers, with tapering in at least 350deg
of the rotation

Also interested in used/broken/other misc direction-finding gear
you might have laying around the shack... (L-pers, SuperDFs, etc)
Any freq range OK, I'm trying to learn more than apply.
(although would like to see something for 10m OTHER THAN a loop)

THANKS!

4225. SSB Power control for the Kenwood TS 440S

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-14 00:00:00 UTC
From: "Gary KF9CM"
Message-ID: <437rgi$sck@sake.wwa.com>
Source record: 110634

AS AN OPERATOR OF THE KENWOOD TS440S HF TRANSCEIVER, I HAVE FOUND
THAT CONTROL OF THE SSB POWER FROM THE FRONT PANEL WOULD
SIMPLIFY THE OPERATION OF THE TRANSCEIVER. THEREFORE, I HAVE
DESIGNED AND INSTALLED A MODIFICATION ON MY RIG AND WOULD LIKE TO
SHARE THIS IMPROVEMENT WITH OTHER OWNERS OF THIS PIECE OF
GEAR. ON THE FOLLOWING IS A DETAILED DESCRIPTION OF THAT
MODIFICATION.
----------CUT----------

KENWOOD TS-440S SSB CONTROL

WITH THE FRONT PANEL CARRIER CONTROL KNOB

THE KENWOOD TS440S HF TRANSCEIVER IS PROBABLY ONE
OF THE BEST ALL AROUND RIGS FOR MOBILE OR PORTABLE
OPERATION, AS WELL AS A GREAT BASE RIG. WHILE THE
KENWOOD TS 440S IS A GREAT LITTLE RIG, IT DOES LACK
A FEW OF THE IMPROVEMENTS THAT THE ARE STANDARD IN
THE OTHER RIGS. ONE SUCH IMPROVEMENT IS CONTROL OF
THE SSB OUTPUT FROM THE FRONT PANEL. BEFORE THIS
MODIFICATION THE ONLY WAY TO ADJUST THE SSB OUTPUT
WITH OUT AN EXTERNAL CIRCUIT WAS TO DISASSEMBLE
THE BOTTOM HALF OF THE CASE AND ADJUST VR1 (ALC).

ALTHOUGH THIS IS A VERY SIMPLE MODIFICATION IF YOU ARE
NOT COMFORTABLE AT WORKING ON ELECTRONIC CIRCUITS DO
NOT ATTEMPT THIS MODIFICATION.

THIS MODIFICATION INVOLVES JUMPERING THE CATHODE OF D48
TO THE ANODE OF D51 ON THE IF BOARD.

1. REMOVE TOP COVER EXPOSING THE I.F. BOARD

2. LOCATE J28. IT IS A TWO (2) PRONG PLUG VECTORED
APPROXIMATELY 2 INCHES FROM THE BACK OF THE I.F.
BOARD AND IN THE CENTER OF THE BOARD. D48 IS
LOCATED JUST TO THE RIGHT OF PLUG J28.

3. NOW LOCATE J19. IT IS VECTORED APPROXIMATELY TWO (2)
INCHES FROM THE FRONT AND IN THE CENTER OF THE BOARD.
D51 IS LOCATED IN BACK OF PIN #8 COUNTING FROM THE LEFT.

4. PREPARE A FIVE INCH PIECE OF #22 HOOKUP WIRE BY STRIPPING
AND TINNING THE ENDS OF THE WIRE APPROXIMATELY ONE FORTH
OF AN INCH ON ONE END, ONE EIGHT OF INCH ON THE OTHER.

5. CAREFULLY APPLY SOLDER TO THE TOP OF D51.

6. CAREFULLY SOLDER THE ONE EIGHTH INCH END OF THE PREPARED WIRE TO TOP OF D51.

7. GENTLY FORCE THE OTHER END OF THE WIRE INTO THE TOP OF PIN #1 OF J28. PIN #1 IS THE ONE ON THE LEFT OF THE PLUG.

8. REASSEMBLE THE COVER.

WITH THIS MODIFICATION YOU CAN SOLDER THE WIRE TO THE FOILS ON THE BOTTOM OF THE I.F. BOARD, BUT IT REQUIRES UNPLUGING ALLOT OF PLUGS FROM THE I.F. BOARD.

WARNING: ALTHOUGH THE SWR PROTECTION CIRCUIT IS STILL IN PLACE, THIS MODIFICATION CAN PRODUCE POWER OUTPUTS THAT CAN EXCEED 180 WATTS AND DAMAGE THE FINAL TRANSISTORS SO BE CAREFUL!

stevem@w6yx.stanford.edu (Steve Muther) wrote:

>I am looking for IF amp ICs for use at 455KHz
>which include gain control for AGC.

There is this wonderful device called a bipolar transistor...and you ought to be able to get a stable 50 dB with two devices. Try the 2N5770 (dime substitute for the 2N918). The GB product peaks at about a mil or so, and forward AGC bias is usually a good thing with either of these puppies.

Mouser Electronics (Santee CA) sells 455 kc IF transformers for a buck or so in onsie-twosies.

I've been playing around with this concept to transmit voice (POV)
between two headsets or between a headset and the instrument panel for
a few months now with mixed results. The problem stems from the fact
that She built the human head with such amazing rotational and
translational versatility, that when the pilot turns around to look at
who urped up on the back seat, (s)he loses all contact with the IR
detector. Multiple IR detectors are OK, but not many people want to
rip the airplane headliner apart to put them hither and yon about the
aircraft. Phasing them also becomes an interesting task. And, of
course, the folks with canopies open to full sunlight present just a
bit of a more challenging problem.

I've also tried radio links (remembering that the whole headset-link
has to sell for under $100) and unless one uses rather sophisticated
RF filtering techniques, harmonics from the 10 watt 118-137 MHz.
aircraft com transmitter on chosen frequencies blow the link away --
not good when the link is also the modulation for the com transmitter!
If it isn't a direct harmonic, crossmod and desense will play games
too.

All in all, it is one of the more challenging tasks I've undertaken in
the last 30 years at this game. Any observations?

This should be possible. There have been several articles in QST over the
years on ladder filters. Try researching them. I have dabbled with some
designs a 9 MHz. As I see it, the major problems with the ladder configuration
are lack of symmetry and the fact that the impedance is not an independant
variable.

But the Ramsey kit _seems_ to offer a functional 2M transceiver for MUCH less
money than even a cheap HT, this makes it very attractive to folks without a
lot of money to spend! I might build one but I have ready access to the test
equipment to make sure it's legal though I would probably do so even if I did.
I'm currently studying for the license exams and when I look at the prices for
some of the 2M equipment I have to admit I'm a little put off. Is there a
low-buck alternative (after all 50% off an expensive radio still may not be a
bargain for some) ?

4232. High current PSU's - for free.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-14 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Sep14.125823.110266@ucl.ac.uk>
Source record: 110641

I have sitting by my desk a 5V, 220A PSU. It's switched-mode, regulated, with an adjustment to set the voltage. 230V AC in gives 5V DC out. It's designed to fit in a piece of equipment, so has no meters, but has logic outputs for over-voltage etc. There is also a 5V, 150A PSU and a 5 & 12V PSU of unknown current rating, but as it draws a maximum of 250VA from the mains, that should give some idea.

I acquired these with the intension of using as a heater supply on some valves, but deceided perhaps a 40A heater (5.5 ~ 6.3V) transformer would be better - if I could find one. Any offers most welcolm!

If anyone wants the power supply(ies), please let me know. Otherwise they will be thrown in a skip. I dont want anything for them. They are ex-equipment, and I have no idea if they work, but all look fine, except the 5V, 150A unit which shows a sign of over-heating at some time.

I've tried to dispose of these through the University. If anyone there wants em, they will get first choice, but otherwise first come, first served - although anyone offering a heater transformer might just jump the queue!

They will have to be picked up in person. I've no intension of shipping them anywhere.

You need to know the specifications of the meter you are using.

Some meters have good RF specifications. For example, an HP-410
is rated for measuring AC voltages up to 700MHz. If you have
one of them, just read from the AC scale. Most meters don't go
anywhere near that high a frequency. Upper limit of frequency
response may be 10's of kHz or MHz.

For some meters you can buy an RF probe. For example, Fluke
sells an RF probe accessory to use with their DMMs. Off hand, I don't
remember the frequency response.

Instead of going the analog route, why not try to get your hands on an optical incremental shaft encoder. The quadrature TTL outputs are easily decoded with a shift register and a few gates or a prom. Or you can use a processor. Syncro's, Selsyns, resolvers and pots are all analog systems which are heavy, and noise and drift prone.

Many rotary incr encoders have 1 sync mark per rev to allow you to initially set 0 degrees. A common 200 count/rev encoder will yield 1/800 rev in resolution. We used to use these for absolute position sensing of Bridgeport CNC milling machines X/Y/Z axis position. Shaft encoders wer mounted on DC servo moters which drove recirculating ball-nuts thru a zero backlash toothed belt drive. System position resolution was about .00039" as I recall.

I can probably dig up some of the info for the quadrature decoder and position loop that I designed if you're interested, although it's been almost 20 years.

I read in the VHF/UHF Manual that push pull is the prefered way to build a vhf amp. Push pull is limited to single band but for vhf that is usually all you can do anyway. Its been a while since I read this, but I remember the primary reason for using a push pull configuration is because the tube capacitance in divided in half, making it easier to make a vhf amp. I think this affects circuit Q. I think the push pull also has lower harmonics.

my two cents worth.

Historically, judging from innumerable ARRL Handbook examples, particularly those having to do with linear amplification, triodes do not exhibit the power gain that tetrodes do, witness their (triodes) application with grounded grid design, cathode driven, that typically end up requiring 65 to 120 watts drive for 1000 to 1500 out.
The example cited in my original posting bears scrutiny before the rebuttals fly. The tube data is admittedly not from EIMAC, but that self-same Handbook, whose tube data has not changed for nearly a generation (probably not a typo, but they could be wrong...).
The amplifiers described are functioning units...at 144.

>application with grounded grid design, cathode driven, that typically end
>up requiring 65 to 120 watts drive for 1000 to 1500 out.

Sure, but that is incomplete amplifier data. For example is the amp grounded grid? If so gain has nothing to do specifically with the tube being a triode or tetrode. In that case gain is determined by the ratio of cathode driving impedance to the anode operating load impedance. In other examples:

A non-grid current producing grid driven linear triode (or tetrode) amplifier has a control grid drive power requirement of zero watts! The only power required is to overcome small dielectric and resistive losses in the tube and associated external grid circuitry.

But a triode has much more grid to anode coupling. So if the gain in class A or AB1 is even close to the same, and the feedback in the tube is not properly compensated for, the triode will be less stable than the tetrode. Not only that, but the compensation is much more subject to error if the initial internal feedback is large, as it is with a triode!

A triode is much more critical to neutralize than a tetrode. Since all class AB2 amplifiers become class A when the drive power is reduced, this stability problem can be evident in class AB2 and other class amplifiers (even when they are on the border of class B, or in class C amplifiers that use grid leak bias). The amplifier has to be stable under zero drive conditions (where any operating class may change to class A). As a matter of fact the gain increases in a grounded grid amplifier when drive is reduced because of the increased anode operating impedance!

In other class of amplifier examples (now drawing grid current), the drive power requirements of a class AB2 triode are usually larger than requirements of an AB2 tetrode or pentode. Yet the unwanted feedback is MUCH higher in the triode. The result is added feedback from lack of

internal tube shielding generally makes triodes much less stable than a tetrode or pentode in the same circuit, even though the teterodes have much more gain.

>The amplifiers described are functioning units...at 144.
>

I sighted specific examples either way, and that's where generalized statements like "triodes are less critical for circuit layout than tetrodes because they have less gain" become problems. To be true, that general statement would require so many qualifications it would fill several pages.

Another problem is evident when I looked in the ARRL Handbook. The data is corrupt.
For example, they show a 8875 as having a 27 watt drive power requirement at 550 watts output at 2000 volts in AB2. If you look at the Key to Class of Service, this is listed as class AB2 push pull modulator service, yet that data is close to typical AB2 grounded grid specs and miles from the push pull AB2 audio data!

Briefly glancing at one page of the Handbook, I found errors in 811A., 8873, 8874, 8875, 3-500Z, and 8877 data. That's in six out of 21 tubes on one page, and I didn't even look closely!

> Has anybody practical experience with home made 4 crystal ladder filters
> for SSB ? This is what I am talking about:-

I've built a couple of ladder filters for SSB Rxs and they seem to work quite well. A good source of information is "W1FB's Design Notebook" published by the ARRL. The last two chaps. are reprints from QST. You will get *much* better results with 6 or 8 xtals, although the filter I built with 4 was quite usable. I used a different design technique, which was published in the RSGB's RadCom a few years ago, which uses different C values, rather than having them all the same. This design lets you trade off bandwidth and I/O impedance. I've just found the details in my notebook:

```
----- X ------ X ------ X ------- X ------
| | | | |
C0 C1 C2 C1 C0
| | | | |
----------------------------------------
```

Cap. coefficients are:

C0 = 0.4142 C1 = 1.82 C2 = 2.828

For SSB X should be between 8 and 10 MHz (Z = 800R - 1K).

To calculate the caps. multiply the coefficients by 1/(2*PI*f*R) where f = xtal. freq. in Hz, R = I/O impedance in ohms. I keep meaning to do some experiments with some of the test equipment we've got at work, to see which is best. The above circuit needs good matching for the I/O impedances, I think ladder filters are much more critical than lattice filters in this respect.

>
> my two cents worth.
> chuck sherwood
> sherwood@cig.mot.com

Yes, it is the preferred way in some applications to build a vhf amp
because it tends to halve the tube capacitances. There are other ways to
deal with the C, which the referenced Handbook amp used, though I can't
recall what it was, and if I go look it up, I'll lose my connection...
And the push-pull also cancels even order harmonics, which may be academic
if the single ended design is done right, though I note your orgs hybrid
amps for CATV and cellular are universally push-pull for those reasons.
Push-pulls can be built for multiband, classically (at HF) using plug-in
coils, perhaps you could build one using some humongous double pole switch
to bring in the inductors (don't key it while switching...).
The complexities of the mechanical design requirements make me prefer to
build two in parallel; a rigorous parallel design can make the even order
harmonic advantage that push-pull designs have an academic point.

I would really appreciate any help or info on this project. Maybe somebody here has built something similar to this, and could E-mail me tips or schematics but do not post for my benefit because I do not frequent this group.

Okay, I need a DTMF pad hooked up to a inexpensize short range transmitter walkie-talkey, homebrew,or somthing like that. I need to have my reciever fire a relay or solenoid or something when the proper 4 digit code is entered. P.S. must be portable (DC) My problem is I have little expertise, but I could have somebody build it properly if it is too involved. Tips on where to salvage circuts from for this are also appreciated.

Thanx. E-mail me

Message-ID: <sherwood.811087229@oribi>
Source record: 110653

People,
I need some help. I have always wanted to build an amp. I have ran
across a supply of tubes and would like some opinions.

One is the 4-1000. This seems like an old reliable tube. There are many
articles to copy. However it is 30 year old technology(I have a construction
article for a 3-1000 in a 1964 handbook), so I'm wondering if I should
consider the ceramic tubes.

I can also obtain 4cx3000As. All the information I have is 10 pages from
the data book. Can this tube be ran grounded grid and grounded screen
like the 4-1000? The application notes only talk about grid driven.

I can deal with solid state supplies, but I'm pretty lost trying to build
a 500 volt regulated supply for the screen. Can anyone help me out here?
Seems to me that a grid bias supply is also required.
How about overcurrent sensors? Are they also required for grid and screen?

Assuming that this tube must be used grid driven, how critical is the layout?
Will it be a power oscillator without super critical shielding?

It appears to me that the 4cx3000 will be a lot more work. Since it would
be ran at considerably less than it capable of, maybe its not worth all
the extra work. Opinions please?

You could use an IR arrangement, just use a white ceiling to bounce the light off. It works with my remote. You might have to increase the IR leds a bit, but it should work.

Digikey sells some 300 MHZ transmitters/receivers. They seem intended for remote unlocking of things, but you can use them as a regular serial stuff.

I have a set that I am trying to use to sned data on my hot tub to my PC, I haven't gotten far with it though...

The following is a list of military transimitting equipment. The BC
191's of course have 4 211/VT4C
each. Three of the four in each one look new, and I had planned to take
them all out. So bid without those
tubes included. If you want tomake an offer with the tubes left in,
include that as well as a bid without
them.

BC191E with TU-6B which tunes from 3000-4000 KC (hard to find)

BC191F with TU5N which tunes from 1500-3000KC (also hard to find)

T-20 in black tunes from 3-4

T-20 in silver tunes from 5.3-7

The next three are in a single rack. They have transformers on the rear of
each that unplug leaving the
original socket.

R-24 marked MT-7 tunes from .52-1.5 three antenae jacks black in color.

R-24 marked Western Electric BC-455B tunes 6-9.1 silver in color.

R-24 marked Western Electric BC-453B tunes 190-550 KC silver in color.

R-24 black tunes .52-1.5 this one is in it's own single rack. Has a
removable transformer on the back
which would leave it with the original socket

Radio receiver BC966A

Radar unit SN36A (I know nothing about this thing)

Wireless set No 19 MK II supply unit No 1

>consider the ceramic tubes.

The 3-1000 and 4-1000 are reliable tubes but are a tad unstable unless you are careful. The self neutralizing frequency is pretty low in both tubes because of the long grid leads and grid structure. The 811A, 572B, 3CX1200A7 and D7 fall in this class also.

>I can also obtain 4cx3000As. All the information I have is 10 pages from
>the data book. Can this tube be ran grounded grid and grounded screen
>like the 4-1000? The application notes only talk about grid driven.
>
That isn't a good choice for grounded grid. The control grid will likely "hog current". Adding grid and screen voltage will help, even if the tube is still cathode driven. A much cleaner and nicer grounded grid tube of that general dissipation is the 3CX3000A7 or F7.

>I can deal with solid state supplies, but I'm pretty lost trying to build
>a 500 volt regulated supply for the screen. Can anyone help me out here?

They are a pain at times. I use a shunt regulator with HV transistors and operate the source from two times the desired voltage (or more) through a series resistor. That limits the dissipation to the standing dissipation of the regulator.

>Seems to me that a grid bias supply is also required.
>How about overcurrent sensors? Are they also required for grid and
screen?
>

Some dissiaption limiting method is ALWAYS required, unless you are a fool. Stiff voltage regulation is also required, except for the CB band ;-) where splatter doesn't matter.

>Assuming that this tube must be used grid driven, how critical is the
layout?

>Will it be a power oscillator without super critical shielding?
>

You can use a parallel NON-INDUCTIVE grid swamping resistor and drive the grid. The value of the resistor for a class AB1 amp is given by the formula (Eg sqrd) over 2Pd. Where Eg is the bias voltage and Pd is the drive power available. So with 300 volts of bias and 100 watts of drive the grid resistor should be...(300x300) over (2x100) or 450 ohms.

This stabilizes the circuit, but you should still use good techniques like grounding the tuning and loading caps to common sheet metal with the socket (do not ground to front panel), keeping leads short, and grounding the screen well for RF. If you don'r swamp the grid heavily you need to neutralize the PA.

>It appears to me that the 4cx3000 will be a lot more work. Since it would
>be ran at considerably less than it capable of, maybe its not worth all
>the extra work. Opinions please?
>
By the time you are done with the screen supply, the bias supply, the expensive socket, and the rest of the messing around it is generally cheaper to buy a new 3CX1200Z7 or 3CX3000F or H7. If the grids are directly grounded in these tubes (zero lead length to chassis) they are totally stable without no external supression in good layouts. They require no expensive sockets or collets, they drive with 100 watt exciters, and provide excellent IMD performance.

>converted to this mode. Of course we are looking at inexpensive and
>reliable radios.

You want the Tekk KS-900. It's designed for 9600 baud data, and it's cheap.
Or you can use the Kantronics D4-10. It's also designed for 9600 baud data,
but not quite so cheap. Or you can butcher an old Micor or Mitrek, though
opening up the IF bandwidth is not trivial if you want good performance.

QST says that of the Japanese radios you want an all-mode since
they usually avoid the synthesizer loop bandpass problem by
modulating an IF stage. They also raved about a new, and expensive,
Azden that's designed for 9600 baud data and FM voice.

Most of the Japanese radios advertised as "9600 baud ready", aren't.
That's just advertising copy, not engineering. It usually means they
put a jack on the back labeled "data", but didn't do any of the
bandpass modifications necessary to properly handle 9600 baud, IE
phase linearity sucks. A case in point is the Kenwood 733. While many
have tried to use them at 9600 baud, the BER is disappointing. And QST
gagged over a couple of Icom models too.

You want a direct FM radio, preferably crystal controlled or IF
modulated, with a receiver IF filter that's gentle and fairly
broad in order to have a reasonable phase response. IF filters
generally suffer severe phase linearity problems near their edges,
so you need a filter that's broader than the modulation would indicate
in order to stay near the filter center and avoid the phase errors
out at the edges. A 30 kHz bandpass seems to work well for 9600 baud.

Unfortunately, SNR and adjacent channel rejection suffer with the broad
gently sloped filters, so you'll need more than expected signal strength,
and a greater guard band, in order to get through with a low BER. This
is a result of the decisions made for the modulating signal in order
to use it through voice grade FM radios. There are much better modulation
forms that could be used with purpose built radios. An example is the
MSK used with the 56kb RF modem. More nearly ideal filters can be used
with this modulation than with the K9NG/G3RUH modulation, but voice
grade FM radios can't be used with MSK so you need purpose built
data radios.

Interestingly, QST found that *overdeviating* the voice grade radios often resulted in lower BER at 9600 baud. This is contrary to the experience with 1200 baud where low deviations generally work best, IE 3 kHz instead of 5 kHz works better for 1200 baud. It may be that a form of limiting occurs in the non-linear IF filters of voice grade radios with hot 9600 baud modulation which sidesteps some of the phase linearity problem. If you try this, watch total occupied spectrum, however, to make sure you stay within the limits for the band you are using, IE don't try this at 2 meters.

Ramsey and spurs and harmonics? A friend once built one of their 40 meter QRP transmitters. I tested it on a $5,000 communications monitor and it showed that the second harmonic was 20 dB down from the fundamental, clearly contrary to FCC rules. I later verified that figure with a $10K comm monitor, and later with a $25K Hewlett-Packard spectrum analyzer. The pi net filter was a simple 3 element design, with odd component values to boot. (All component values were correct, ie, they had the proper parts in the kit--I verified actual values.) Instead of letting him put the rig on the air as-is, I tacked on an additional filter in series with the existing one, and the output is now much cleaner, with the second harmonic about 51 dB below the fundamental at a very small cost in added insertion loss. Moral--if you build a Ramsey QRP transmitter, you might want to have someone check the spectrum if they have the equipment. I don't know if this problem appears in other bands, but it certainly exists in the 40M version unless they made design changes in the last 2 years.

Someone recently recommended the ham library room at Maryland Radio Center in Laurel, MD as a good source for checking out old QSTs, etc. Sadly, the libary is toast--the store will be moving to a nearby building in the next many months, and there will be no room for the library. The owner has made arrangements to give it to a ham club in Baltimore, BARC I believe, which will eventually make it available to the ham general public. It is slated to be removed from the MRC premises on the 16th of Sept.

While I think modified commercial gear is probably a good thing, it's somewhat less accessible to most of us, because we have no history with it. For instance, I have no idea which GE radios are easy to convert, and which aren't. Same goes for Motorola. I mean, Micor, Motran, Mitrek, etc. mean nothing in themselves, and even less when I'm looking at a radio at a swap meet. In some cases, I can't even tell if I've got all the pieces.

There's been lots of good information put forth here, and on the land-mobile mailing list, but you people who know the details need to put together a FAQ about all of this. The information is out there, and it dribbles in from time to time, but it needs to be put together.
Thanks and 73,

I've no idea, but the data sheet would surely say? If not, I assume its not
reccomended. The 'typical operation' section usually tells you this.

> I can deal with solid state supplies, but I'm pretty lost trying to build
> a 500 volt regulated supply for the screen. Can anyone help me out here?
> Seems to me that a grid bias supply is also required.
> How about overcurrent sensors? Are they also required for grid and screen?

You need to be able to sink and source current on the screen supply. John Nelson
GW4FRX shouws in the VHF/UHF DX book (DIR Publishing), how to do it for
4CX250/350 screen supplies
of either 300 or 350V. I've built a shunt stabilier using a rather expensive
high voltage/high-pwer FET. It works, but it not quite good enough yet for me to
be willing to advise you copy it exactly. That provided -325V, for a grounded screen
amp, to put -325V on the cathode, with the screen earhted.

> Assuming that this tube must be used grid driven, how critical is the layout?
> Will it be a power oscillator without super critical shielding?
Assuming you take reasonable precautions - ie put the grid and anode in different
compartments, I doubt you should have any problems, but I've never used the 4CX3000.
I've no idea of your frequency of interest, so cant comment much.

> It appears to me that the 4cx3000 will be a lot more work. Since it would
> be ran at considerably less than it capable of, maybe its not worth all
> the extra work. Opinions please?

Does the 4CX3000 need a special base ? If it does, and you dont have it, that might
be a deceiding factor. Bases usually cost much more than the valves, and are
much less easily available on the surplus market.

There was a circuit in some earlier (1991 for sure, probably others too) ARRL handbooks for a grounded screen, signle 4CX1000A. That might be worth looking at, since it does not require an expensive socket with a built-in screen decoupling capacitor, it can save a lot of money. I've tried to build an amp with a pair of 4CX1000A's in push-pull, grounded screen, using home-made bases. However, making bases is not easy! Its very time consuming, unless you happen to be an expert on a lathe and milling machine - which I'm not. However, it can be done, and can save you a small fortune.

Yes there is! Ten-Tec has a real nice 2 meter transceiver kit for just a few bucks more. Digital read out, nice case, and complete and ready to go. Call Ten-Tec for their catalog.

>In article <435kf3$efi@calliope.wln.com> electron@rs6a.wln.com (Mike Brothers) writes:
>>by David A. Wolf mentions building a "turnstile antenna" using copper
>>wire and pvc pipe. Complete construction details appeared in the next
>>issue. The problem is, I don't have this issue!
>A turnstile is a simple antenna, just two crossed dipoles mounted
>a quarterwave above a groundplane (usually made from window screen
>wire stretched on a frame). Two 1/4-wave sections of 75 ohm coax,
>one to each dipole and joined by a coax Tee to a 50 ohm cable to the
>receiver is how you feed it.

One additional note: the two dipoles are fed out of phase to induce circular polarization. The rotational polarization can be switched by determining which antenna has the longer feedline to the tee.

>There are much better antennas. The popular eggbeater style is
>better, a Lindenblad or a quadrafilar helix are better still
>while still being omni-directional (and circularly polarized).
>Steerable yagis are better yet. Cost and complexity rise with
>performance, however, and the turnstile is one of the cheapest
>and easiest antennas that will offer improvement over the scanner's
>whip.

My observations verify this; the turnstile worked much better than the terrestial whip. Another possibility is the egg beater antenna, which is (I think) vertically polarized on the horizon, and circular in the vertical direction. Lindenblads, like the turnstile, are easy to build as "PVC specials". I build a 300-ohm TV twinlead-based turnstile for the whopping cost of about $10. Quadrafilars are more difficult to build.

>For passes below 30 degrees above your local horizon, however,
>a gain vertical antenna will outperform the turnstile. That's
>because the turnstile has maximum gain straight up, where you
>need it least because the satellite is closest to you at that
>time. The vertical offers gain toward the horizon, where you
>need it most because the satellite is furtherest from you at
>that time.

This is true. The biggest improvement I noticed was the elimination of cross-polarization fading while the satellite was well-above the horizon. Fading, of course, led to fading ripples in my imaging. I figured that for the interim, I was interested in seeing images of myself, so horizon fading was acceptable.

4259. Re: Need advice on amp building

Newsgroup: rec.radio.amateur.homebrew

: amp, to put -325V on the cathode, with the screen earhted.

The active shunt regualtor design shown in Figure 11.2 of the book is "plug and play" for either + or - output, because the whole thing is powered from the HV supply itself. The two power FETs are IRF840P and cost about $5 each.

One FET is the shunt stablilizing element, while the other is a constant-current source from the unstablilized HV supply. The constant-current FET requires very little "headroom" voltage, improves the regulation and makes the whole unit virtually short-circuit-proof.

I do strongly recommend an active screen stablizer such as this. Instead of struggling to make the regulation good enough using VR tubes or zeners, an active regulator actually gives far better regulation than the tube needs. You can then afford to add series resistances like meter shunts, parasitic stopper chokes etc, and still have good-enough regulation at the screen terminal where it matters.

Some time ago I modified the Fig 11.2 circuit to incorporate an opto-coupled screen current trip circuit inside the voltage feedback loop. It's helped keep the pair of 4CX250BMs running at 1kW out on 432 for several years with no signs of distress. The screen current trip is very valuable because it protects against almost anything that can go wrong with a tetrode.

"In beta" is a new version configurable for + or - 250 to 600V stabilized output. It also includes the opto-coupled current trip protection. I'd like to write it up for a magazine, but am waiting until I've had some feedback from real users. There are several copies of the board masks and alignment notes already out there, but up to now all the prospective testers have got diverted to other projects.

If anybody is *definitely* going to be building a screen regulator
right now, and would like to field-test this circuit, please
let me know.

Source record: 110671

Due to limited space on my city propery, I have considered building a helical vertical for 80 m. I have seen a similar design for 160 meters but there are a few things that confuse me. I hope you can help me...

They say for 160 m, to get a 20-25 ft length of PVC pipe and wrap HALF a wavelength of wire on the full length of the pipe. They then say that this will give you a QUARTER WAVE resonant vertical. Does that mean if I use a FULL wavelength on a 50 ft length of PVC pipe, that I can have a HALF WAVE resonant vertical ? If so, does this mean I will not need the ground radials for the HALF WAVE version. Naturally both versions are end fend and tuned at the bottom for the best SWR. A capacitive hat is placed on top to prevent the 'tesla' affect, so to speak.

I have no experience at all with helicals so ANY useful info would be nice. By the way, if there is a way for me to avoid use of ground radials with a vertical helical, then please tell me how to do this. I do not have the room either for spreading wires all over my yard, and using the water or sewer lines may or may not work. I need something dependable and efficient, since I am running QRP (in the 1/4 watt region).

Look for a used or new 10m-->50Mhz transverter. Exchange the xtal
from a 22Mhz to a 23Mhz xtal. You may have to tweak the oszillator
circuit a little but it should work fine. Dont forget,that this
transverters mostly have 10dBm (10 mW) input. You may want to build a
attenuator or reduce your drive with other means.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

4269. crystal drive specs How to measure?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-16 00:00:00 UTC
From: ptracy@aol.com
Message-ID: <43evsb$8jh@newsbf02.news.aol.com>
Source record: 110578

Here we go with project #12554. I have built several crystal oscillators mostly of the colpitts and pierce variety. One spec that I never complety understood is Drive power to the crystal. My usual approach to setting "drive" is to adjust feedback by whatever means that seems to work to a point where the oscillator doesn't start some times, and then back up. I can measure ESR in a roundabout fasion using a signal genertor, a resistor, and a FET probe. I no longer have access to a vector voltmeter or crystal impedance meter. I can and have measured crystal current using a Tektronix current probe. I am just not sure how to go about calculating the crystal drive to make sure it's within acceptable limits. Is it as simple as I^2 * esr? Nahh, couldn't be. Unless I am mis-using the current probe, the current and voltage are nearly 180 deg out of phase. If one applies ac power triangle formulas, then the TRUE power is much much less than the apparent power, with reactive power being almost equal to apparent power. Any help?

Thanks, Pat - KE1C

While a FAQ is a good idea, the best thing you can do is to buy service manuals for several of these radios and study them. All the information you need is in there, and you can learn a good bit about radio design from studying those manuals too. You'll often find someone with a pile of manuals for sale at hamfests, or you can order manual copies from Hi-Manuals, or even the manufacturers. When these radios were current production, the manufacturers still had some respect for the service tech, and they did an often splendid job of explaining the circuit theory of the units. Today, manuals often just have a fault tree offered without underlying explanation.

4271. 4CX1500 redux

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-16 00:00:00 UTC
From: rst@tetrault.com
Message-ID: <rst-1609951145080001@squaw-d116.sierra.net>
Source record: 110580

Nolo Contendere,
my generalizations did not include several qualifications made by the citation; that power gain of most grounded grid amplifiers is not as great as tetrode amps.

In any event, it was prompted by the series screen neutralization thread. My example cited used a directly grounded screen and a cathode floating for DC. The argument being that with the "high power gain" of a tetrode, and with the significant dimensions of the screen at 144, it was highly probable that the screen could not be "grounded" capacitively at that frequency. Having to AC bypass the cathode is not as problemmatic as for the screen, as any "floating" of the cathode would only add degenerative feedback and subsequently raise the required drive power. The example mentioned a very expensive version of the tube and socket that was designed for grounded screen, they deigned to fashion a reasonable substitute.

The example also used a pair of quarter wave lines at both grid and plate, arguing that the impedance would drop towards zero as the frequency changed, preventing the grid from floating off to some undefined impedance for frequencies off resonance.

These were all details of a design that displayed 40 dB reverse isolation while generating 25 dB of forward gain, with no neutralization. That is a significant achievement, and my earlier postings intended only to make note of this amp example.

Frankly, the thread for screen neutralization went on so long (IMHO) that I was prompted to propose an alternative. Albeit that the Handbook data is wrong, the example cited frankly states they got 1400 out for 10 watts in regardless of 4CX1000 or 4CX1500.

I have seen many older Class C amplifiers, push-pull triodes, say 833's, that gave an easy kilowatt for ten watts of drive, but they were swamped *and* neutralized. There were paralled 813 tetrodes or single 4-400's giving the same output/drive performance, showing the essentially moot choice one could have if the triodes were not GG.

I wonder what the state of kilowatt level tube development would be like if we had not had the plethora of 100 watt output rigs, but instead only 10 watts. The ease of GG application and broadbanding of the input circuit allowed many amps out on the market and probably made a lot of people happy, and raised the intermod level, that drove people to better receivers, and so on.

It still bears a review by the poor guy who originally asked the question about PP 4CX1500's...I have frequently referred to the amp as a motivator for when I finish my 20 watt HF transceiver.

Regards

I am looking for a manual or schematic for a AM-1178/GRC 400-600 Mhz Amplifier/Multiplier.

Or does anyone have any info on converting this over to 432 mhz SSB amp? It has a nice pair or 4X-150's in nice tuned cavities that should work great.

Any info would be appreciated.

Since you mention the numbers 50 and 300, I assume you are talking about
transmission lines? That you wish to match a 300 Ohm transmission line
to a 50 Ohm transmission line?

Is this for transmitting or receiving?

How much power?

I've built several ladder filters in 4,6 and 8 pole configurations. My experience is that the 4 pole configuration comes out decidedly non-symetrical, but that shape improves as you add sections. The 6 pole configuration was good, and the 8 pole configuration was near perfect. Shape factor of 1.2:1 is achievable.

Problem with large filters like this is that there is a lot of interaction between variables, and its hard to optimize without a good spectrum analyzer/tracking generator setup.

One quick and dirty way I've done it is to measure the output power of
the oscillator into its design load (milliwattmeter or e^2/r).
Measure or calculate or estimate (SEWAG) the power gain of your device
as published by the mfg. at your freq., voltage, and current level.
The power drive to the crystal is the output power reduced by the
power gain of the circuit. It seems like going to CHicago by way of
FOrt Worth to do it this way, but it is a pretty foolproof method of
approximating.

If you aren't at least 10 dB below the max drive limits of the rock,
you are going to get aging and drift problems. I usually shoot for 20
dB below max limits.

Hi!

Could anyone tell me how to modify Motorola 'Director' voice pager?
It's frequency is tuned to 462.825MHz and it has 18.49480Mhz X'tal.
It seems it's IF is 450KHz. Local OSC seems like 462.375MHz(?) generated
by 18.4948Mhz X'tal... 462.825MHz-462.375MHz=450Khz??

If anyone know how to calculate the X'tal frequency in order to bring
down to hamradio band, please let me know!

It has two mechanical resonace to open or turn on the voice. (533.9 hz &
600.9 hz) (two-sequence-tone-decoder.) I felt the age of the receiver, it
only contains two ICs and a lot of transistors. Anyone know what is
M6778 and 79G08 ICs for?

Or, if you have any information regarding to the voice pager, please let
me know!!

Thanks in advance.

4284. Modiying an old tube AM radio with pencil tubes, results

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-18 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDF2wnl.1Br@netcom.com>
Source record: 110593

I have a few "pencil" tubes, or "sub-mini's" as they are called.
Mostly from mil surplus stuff. These are about a 1/3 inch diameter
and about 1 1/2 to 2 inches tall, one style has 8 pins in a circle,
another style is 5 or 7 pins in a straight row.

I've thought of using some of these sub-mini tubes in an AM BC band
radio, like the old AC/DC "AA5" tube radios. So I took an
otherwise ordinary AA5 tube radio (AA5 = "All American 5 tube")
and decided to modify it to use some pencil tubes. First mod was
to change the IF amp tube (12BA6) to a 5840, which came out of
a mil IF strip, guessing it would work in the AM radio. And it
actually did work, though I found I needed a tube shield to keep it
from oscillating. Worked well, actually, maybe a bit better than
the 12BA6 did. I measured the heater current with a DVM and a 6.3
volt supply, and it was close to the 150mA of the AA5 heater string.
Checked it in the radio, voltage a bit high, so I paralleled a 330
resistor to get the voltage and current to spec.

A few days later...:

The AA5 tube radio I modified with a 5840 sub-mini tube in the IF stage
recieved some more sub-mini tubes today. This time I replaced the
12AV6 det and 1st audio tube. With two triodes, 5703's. I also
had some twin triode sub-minis, but a restriction I had to adhere to
is that the heater current should be around the 150 ma of the AA5
string. One of the triodes became the 1st audio stage (50C5 driver),
with a grounded cathode and self-biasing grid. It draws a bit more
b+ current than a 12AV6 does, as the voltage on the plate measured
about 18V, but it sounds fine. And enough gain. The other triode
became the diode detector. Cathode grounded, plate grounded, grid
tied to the IF transformer. A tube knowlegdable friend suggested the
grounded plate, to act as an RF shield to keep the harmonics of the
rectified 455KHz IF signal from causing tweets at 910Khz radio stations.
Couldn't find any tweets there yet tonight, tommrow I'll try a daytimer
station at 910. I used a wire wrap socket, and needed to spread the
leads on the 5703's a bit (didn't have any proper in line tube sockets).
Bent the wire wrap posts to reach the tube socket holes on the AA5's
circuit board.

Radio is working well, here in northern NJ, I'm listening to "84 WHAS"
which I think is in the South somewheres, near an Interstate 65 or such.
Propagation must be pretty good tonight.

The AA5 design must have been an excellent design job, to take the above
"crude" mods, and still work well.

4285. Re: (HELP)CORE CHOICE FOR COIL DESIGN

: ; I am working on a radio design for thru the ground radio using coils as the
: ; receiver and transmitter antenna.
: ;
: ; I need a impedance matching transformer between the coil and the receiver. The
: ; problem is that I need a very high al value (Large amount of inductance).
: ;
: ; Powder Iron toroids are out of the question because of size. My other choice
: ; is a ferrite pot core made by Amidon which is type material 77. It is of the
: ; right size and will accommadate the windings. This material is primarally used
: ; at higher frequencies than the 31 KHZ I wish to use.
: ;
: ; Will this type of core material (type 77) cause excessive core loss (poor
: ; sensitivity due to core loss at receiver impedance match) at the frequency I
: ; wish to use on receive (31KHZ).
: ;
: ; If so, Then can you suggest another core manufactor and type material.
: ;
: ; Danny Britton
: ; QB7@ORNL.GOV

: The type 77 pot core is a good choice for this application. Use one which does
: not have a gap.

You might just use a FET buffer to perform the impedance transformation. Since the gate input impedance is very high, just hang a resistor to ground from the gate to set the termination reistance. The impedance at the drain can be much lower, or you can use the FET as a source follower and have the source resistor match the receiver input impedance.

>repeater? Do I have to make nany other changes?
>
>-WaiWong
>

Any tone and voice beeper can be put on an amateur frequency if they are
not too far away; in your case it might be easier with a beeper already
in the 141-143 MHx region; 152.480 is a bit high and you may have to
change a few caps and coils...

We have 28 beepers in service on our vhf and uhf repeaters; our controllers
are Scom 6K and they support 5/6 tones code required by the
Motorola BPR2000 beepers we have and 2 tones for the NEC beepers.
It is easy to reach any Ham equiped with a beeper in our Club;
we just send a 4 digits DTMF code to the repeater's controller and
it send the proper codes to the beeper we want.

The only problem with listening only, is that most of these beepers don't
have a squelch circuit and you are going to hear a "hiss" all time the
repeater is not transmitting.

>the crystal drive to make sure it's within acceptable limits. Is it as
>simple as I^2 * esr? Nahh, couldn't be. Unless I am mis-using the

Yes it is that simple. Be sure to excite the crystal at the specified
drive power when characterizing its ESR, because ESR is itself affected
to some extent by drive power.

>current probe, the current and voltage are nearly 180 deg out of phase.

If the crystal is being operated in "parallel" resonant mode, it will
look mostly inductive, so the current and voltage are 90 degrees out of
phase. The thing to do is measure current and ESR and forget about
voltage.

>If one applies ac power triangle formulas, then the TRUE power is much
>much less than the apparent power, with reactive power being almost equal
>to apparent power. Any help?
>
>Thanks, Pat - KE1C

Most oscillator designs subject the crystal to rather high drive levels
(several mW.). The easiest way to avoid this problem is to either run
the oscillator on a very low voltage supply, such as 3 volts or put
clamping diodes on the collector to limit the voltage swing. Otherwise,
you're stuck with using small capacitors in the circuit which decreases
the stability. In the high precision oscillators we make here at
the Hewlett Packard Santa Clara division, we run the crystals at 40
microwatts to minimize phase noise, but the crystal people tell us
they consider that an astronomical amount of power and wish we could
hold it down to 1 microwatt! In the high precision oscillators, we
use an AGC circuit to precisely set the drive power.

Hi, Jim

Call micro-semi Corp. and ask for publication PD-600. It is the PIN Diode
Designers Handbook and is VERY handy. And yes PIN diodes can work in
Power Amps up to 1K Watt!

AMATEUR RADIO GONE COMMERCIAL!!!

I recently picked up a new study guide for the Advanced Class test
to prepare myself for taking the upgrade examination.

While reviewing the question pool, as I neared the end of the list,
I found two very disheartening questions, both of which the answers
were related directly to proprietary data and information.

I was so mad that I tore the book in half and threw it in the trash.

As I no longer have the book, I can't put the two questions here, but
the questions were related to antennas and the method of moments, which
is definately proprietary information and has no place on the exam.

How can such proprietary questions be put in the question pool and can
I request a test that does not contain either of these two questions?

After 36 years as a ham, I am seriously considering leaving the hobby
before it becomes totally commercialized. Many 2-meter repeater sysops
are already allowing so much foul language and grossness to pass through
their repeaters that they are degredating the amateur image beyond repair.

VECs have incorporated as "Corporation of Volunteer Examiner Coordinators"
and are trying to copyright the question pools, the ARRL sent a petition
to the FCC to have all expired amateur licenses reinstated with no
penalties and no retesting. What will the ARRL pull next, crossband
repeaters between the CB and Amateur services?

How much will your license cost when it is turned over to the private
sector for testing and licensing? How much will your yearly dues be to
maintain the one or two bands that we have left after commercialization?

At least the FCC had enough incite to delete a few blatantly proprietary
questions from the last exam pool, but as usual, they didn't complete
their job and allowed the ARRL to squeeze in a few more advertisements
into the question pool.

4294. HV supply chokes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-18 00:00:00 UTC
From: Michael@diamonds.batnet.com
Message-ID: <Michael-1809951037450001@diamonds.batnet.com>
Source record: 110603

I'm building an HV supply for a microwave source. I need a vendor for filter chokes with at least 5Hy inductance, at a maximum current of about 800 mA. Winding-to-case breakdown isn't too critical, as I can mount the choke on
a dielectric support. Can anyone recommend a source of chokes (and HV transformers as well)? Thanks for your help.

Shack cleaning sale again revised! Gotta make room for more stuff
coming in.

FOR SALE or TRADE: Stoddard AN/PRM-1 Radio Test Set. With
storage trunk for receiver, adaptors. Also have Remote indicator assy
and AC power supply, but NO storage trunk for them. This is an RFI
(Or in modern language "EMI") receiver. It has the capability of
measuring Field Intensity in microvolts per meter via a whip antenna
or a loop antenna. VERY handy for finding interference sources,
measuring field strength etc. in the range 150 khz to 25 Mhz in 7
bands. I also have the original Technical manual/Depot manual.
These are fairly rare, I have only heard of one other one in the
last 25 years. They have been largely superceded by the more modern
Stoddart solid state version. (Tucker had them for around $5000!!!)
Will sell for $250 plus packing/shipping

GENERAL RADIO Model 650 'Antique' Impedance bridge, Cosmetically fair
to good. Works! Measure L/C/R. Sell for $50 plus shipping/packing.

GENERAL RADIO Model 1330A Bridge Oscillator. 15 Khz. thru 50 mhz
in 8 bands. Working OK, cosmetically good. Sell for $60 plus
shipping/packing.

GENERAL RADIO Megohmmeter model 1862C in excellent condition and
working. Missing only two small 'latches' in lid locking system
which does not affect operation. $75 plus shipping/packing.

GENERAL RADIO 722-MD Precision Variable Capacitor, absolutely in
mint condition with fitted wood carrying case. $100 plus packing/
shipping.

Heathkit IT-2250 Autoranging capacitance meter, excellent condition,
$50 with manual plus shipping/packing.

Heathkit QM-1 "Q" meter, works OK, well worn condition, $30 with
manual plus packing/shipping.

Heathkit IG-42 Laboratory Generator, covers 100 khz-30 Mhz., With cable
works fine, good cosmetic condition. $30 plus shipping/packing.

Heathkit IB-2 Impedance Bridge. Measures L/C/R. Well worn
condition, works OK, with manual. $30 plus shipping/packing.

ICOM IC-R1 pocket receiver. Covers .1-1300 mhz., AM/FM/wideband FM,
have original box, carrying cases, rubber duck and additionally BP-83
NiCad battery, BP-90 dry battery box, BC-72 desktop charger, and R1

service manual. Have about $800 invested. Will sell for $400 plus shipping/packing. THIS IS NOT THE "BLOCKED" MODEL, it covers all the cellular channels!

Trade? I am looking for the following: Hallicrafters SX-88 receiver, Hallicrafters SX-100 (late Mark), Hallicrafters SR-75 Transceiver, Heathkit IP-17, SP-17A or IP-32 power supply all in good condition or better.

4296. Need your input for Surplus Land Mobile Radio FAQ

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-19 00:00:00 UTC
From: randolph@est.enet.dec.com
Message-ID: <43n25h$g8u@mrnews.mro.dec.com>
Source record: 110605
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

What the heck, let's make it official:
I'm willing to compile a FAQ, all about those surplus police and taxicab radios and converting them for ham-band use... you know, the ones you always hear on the air 'cuz somebody converted one: Motorola Mitrek, GE Master II, Phoenix, Delta, blah, blah, blah. There's dozens of these things available for cheap money, and I'm sure a lot of us would like to know which ones to look for, and which to skip over, as their performance often beats the imported synthesized rigs!

In particular, what I want to get is information on how to identify the particular models, what band they're on, crystal or synth, whether they're an easy conversion, need a fair amount of work and skill, or are impossible, and how to tell all of this by looking at them and reading the model/serial numbers. Also, it'd be good to know if a full manual with schematics and tune-up procedure is available, from either the manufacturer or a Sam's photofact type publication.

I don't really want to start a database of HOW to do the mods. That would be difficult without graphics, and would occupy megabytes! This should be fairly easy to deduce from the tune-up procedure and other details in the manual.

WHY do this?
1) I'm interested - I've passed over a lot of these at fleas, for lack of any information about what I was looking at.
2) It doesn't seem to exist anywhere else. A lot of hams have some knowledge about some radios, no one has written it all up.
3) Put these radios back to work, and save them from the scrapyards!

So there it is... all info, pointers, literature references appreciated! Send to me at: randolph@est.enet.dec.com

Well the trend of the United States is to do that in everything. For whatever social reasoning, all requirements are being reduced because the latest morality is that everybody deserves everything with moderate effort. No one is allowed to be unsucessful or even average anymore. And when there is no work there is no value to the achievement.

Do you need examples?

The deletion of 1st class license for working on broadcast and special radio services. I watched many less than competent technicians jump from CB into commercial two way and BC markets where their lack of skill and knowlege can cause huge problems.
The relaxation of amateur exams from essay and schematic drawing to multiple choice. The code dropped from one minute solid error free to a few multiple choice questions. And if that isn't bad enough a few *volunteer examiners* will help you out a bit.

Grades in school. In a local school here kids work in teams and are graded against curves. I've seen tests come home with 50% correct and "A's" at the top. They even have forums and question samples to prepare for achievement level tests! We had to take the things out of the blue, but now they rehearse!

Drivers license tests. No road test in this state. Just drive around the parking lot once and that's it!

And the list goes on. We've deceided failure is bad, and so reduced the requirements needed to meet the goals.

>VECs have incorporated as "Corporation of Volunteer Examiner
Coordinators"

Probably the idea is to get as many Hams as they can. There is power and money in it. Look at the money (and mess) that CB brought to some manufacturers. We all have opinions on this, and mine is that there should be a very restricted privilege easy class
for casual users and begginers, but why destroy the entire structure? If the lowest class is made easier, make the highest class more difficult. At least that way people have incentives that remain in place.

An example is a car show I attended. The lowest award was a Bronze, middle a Silver, the highest a Gold. In keeping with this new way of thinking the cars in my class all received Gold's, with one silver. No Bronze awards were given. Some of the Gold's had rust and many incorrect or bad details and missing parts. The Silver award car had holes in the floors. So what is the incentive for anyone to do better? A lot of effort is rewarded the same as a sloppy half-assed effort, so why go the extra mile? That's what it's all coming to Gary, not just in Ham radio.

Peter Dahl is a good source for HV transformers and chokes.

Things to consider:
additional filter caps may be cheaper than a filter choke, and will definitely weigh less
if you put the filter choke in the negative leg, you remove the requirement for HV protection and reduce/eliminate the need for a dielectric standoff
you may be able to find a big filament transformer whose primary winding provides sufficient inductance for your application.

Hi Gary OM,

Hear hear! I could not agree more, with your concerns about commercialization of ham radio. Also, the posts you have received so far regarding the Dumbing Down of Ham Radio, QST, and our American culture in general.
I am almost at the point of canning my ARRL membership after 40 years. QST now has "construction" articles in which all parts are listed as supplied by the author, no theory of operation, no details of the software/firmware, etc. Then it is nothing more than an advertisement, instead of an article. Plus, now
we are seeing many "articles" that are nothing more than advertisements for ARRL
products like the "Radio Designer" software. When I go back and browse through
my QST collection, and review what QST was like 10, 20, 30, and more years ago, it is readily apparent what has happened to QST in recent years.
Remember, the ARRL is really a PUBLISHING house, and they will do whatever the market demands to maximize their success in the PUBLISHING business, and to attract advertisers. That is why the "Equipment Reviews" have always been a joke; they are often very incomplete and almost never say anything "bad" about the equipment being reviewed, when in fact I have used the equipment and noted many glaring design errors and performance or cost-effectiveness deficiencies which were never mentioned in their equipment reviews.

What?

Are you saying that anything dealing with the method of moments is
proprietary information? NEC and miniNEC use method of moments, don't
they? NEC was govt. funded and MiniNEC is in the public domain.
HP, Sonnet, and Compact all have method-of-moment products. If more
than one vendor is using the method, how can it be proprietary? These
folks are vicious competitors --- they aren't licensing it from each
other!

Please elaborate on your objections...

Hi Erwin,

You should be able to use any transverter and drive it from 27MHz.

Yoou would have to replace the main xtals in the transverter to those that suite an IF of 27MHz and then just retune the transverter.

Not a great seperation between 28.000 and 27.000 so there should be little hassles.

Best of luck.

Hi Steve.

Obviously eliminating the license was the correct way to go.

The FCC just forgot to pass a rule reqiring all equipment to be designed to give repair codes. The FCC also forgot to pass a rule requiring directional arrays to give codes if something is out of wack, or codes if equipment was installed haywire or in a manner prone to encourage lightning damage or ground loops. ;-)

Seriously, that example doesn't apply at all to normal First Class employment situations like BC and two way radio.

What you need is the video subsystem of a TV to do this. That's usually a single chip in modern TVs. Motorola and others make these chips, and have application notes for how to use them, or you can just buy a SAMS for a TV using one of these chips and copy their circuitry.

The basic problem is that composite video (we assume NTSC) is a complex waveform encoding luminance information in a baseband analog fashion while encoding hue information in the phase of a 3.58 MHz subcarrier and color saturation information in the amplitude of that subcarrier. You have to recover the phase and amplitude information from the subcarrier, and combine that with the luminance information in a decoder matrix to get RGB. Every TV ultimately has to do this in order to drive the RGB guns of the CRT, so every set has the proper decoding matrix implemented. The only difference for your application is in how you apply sync, and in the levels you apply to the VGA monitor (again we assume a multisync monitor capable of supporting TV sync rates). Those issues are easily addressed via simple resistor networks once you've broken the composite signal down into H sync, V sync, R, G, and B with the TV video subsystem chip.

As far as I know, the method of moments is not a patented algorithm, though of course many programs which use it are copyrighted works of their authors. So I don't understand your beef. You could always calculate using it by hand, or write your own program, if you don't want to buy a commercial version. You'd expect to pay for a pen wouldn't you? Why should you not expect to pay for a more complex computational tool? Of course you *could* kill your own fowl for a quill, and dip it in your own blood to write the exam, but I hardly think that reasonable. As technology has advanced, so has the sophistication of the tools we use to work with it. You don't want the exam *dumbed down* to the level where only hand calculation is convienent do you?

: I found two very disheartening questions, both of which the answers
: were related directly to proprietary data and information.

: I was so mad that I tore the book in half and threw it in the trash.

: As I no longer have the book, I can't put the two questions here, but
: the questions were related to antennas and the method of moments, which
: is definately proprietary information and has no place on the exam.

: How can such proprietary questions be put in the question pool and can
: I request a test that does not contain either of these two questions?

Maybe I'm being too damned analytical here, but how can I hope to carry on a meaningful discussion about this if I don't know what the questions were? How do I know what you consider to be "proprietary"? Do you consider explanations about how electromagnetic radiation propagates to be "proprietary"? Do you consider discussions about how semiconductor devices operate to be "proprietary"? I believe that anything published in a journal, book or dissertation is not "proprietary", and I also believe that anything which is patented is not "proprietary" ... it is _protected_ but not proprietary. Part of the purpose of a patent is to disclose the invention to the public.

The MC1350 is certianly still in production and is available from DC Electronics 1 (800) 467-7736. Their latest calalog list them at $1.95 each.The Motorola Selector Guide lists DC to 45 MHz however I have seen them used suitably in the 6-Meter range.

I have read each of your replies and enclosed my comments below.

To clarify my original post and present my beef more clearly, perhaps the following will suffice.

The two questions in the Advanced Question Pool, as many of you figured out are, A9B09 and A9B10. The first asks "What type of computer program is commonly used for modeling antennas?" and the second "What is the principle of a "Method of Moments" analysis?"

As an antenna designer myself, I was surprised that the question first indicated that the program in question was a "commonly used computer program", so common I never heard of it. From the posts I have read thus far, apparently our Tax Dollars paid for it's inception and private companies are offering it for sale, making it even more proprietary than I originally suspected.

In my course of study to upgrade to Advanced Class, I try to find out everything I can about the questions posed in the exam. When I tried to find out about the "Method of Moments" I initially found nothing about it. I purchased "The ARRL ANTENNA Book" along with a disk containing the computer programs they offer. After reading the book cover to cover and finding nothing mentioned about the "Method of Moments Computer Program", I contacted the ARRL about this supposedly "commonly used computer program" and was informed that I would have to order it for a specific price. Until today, I just figured it was the property of the ARRL, now I find many different private enterprises have claimed something our tax dollars already paid for.

In any case, both of the questions presented in the current question pool are directly contrary to the FCCs goal of giving the public the best possible service at minimal cost.

There are currently 582 questions in the Advanced question pool. Hypothetically, if 1 out of every 10 questions consisted of proprietary type information and this information cost you $29.95 to obtain, it would cost you well over $1,500.00 just to study for your upgrade.

I hope this clarifies my point before the abuse becomes non-hypothetical.

Commentary about replies to my original post:
Donald J. Miller - They don't give it away free either!
Roy Lewallen W7EL - Your two key words were "Brief Description" and "Purchased"...Brief Description is not a computer program and purchased means to me, proprietary.
W8JI Tom - I'm Glad your Eyes are OPEN to the degredation sweeping the nation.

Steve Sampson - Unfortunately, the error codes are sometimes in error themselves and don't apply to every component or problem!
Don Huff - Well put Don, I dropped my ARRL membership back in the '70s for reasons I won't get into here. I will say, they don't even excel in the publishing business. Most of their books are innundated with gross errors.
Gary Coffman - I could buy Kalkwasser at Albert's prices, But I choose pickling lime from Ball, But what does that have to do with the question pool?

The questions were A9B09 and A9B10!
Proprietary means either the product is copyrighted or patented and offered
for resale by a private firm or organization and the contents of which are
not freely distributed.
No, in order to sell a new semiconductor, the manufacturer freely publishes
the data sheets on same.
You can feel that way if you want, but I hold three US Patents myself and my
products are definately proprietary, meaning I don't allow anyone other than
myself to produce or sell my products, however, I do publicize every single
thing about my products in their respective patent abstracts. But for
seventeen years they are my proprietary product.

You think so, most patents do not disclose the operation of any device, nor the exact manufacturing specifications. Patents are usually generalizations to extend the scope and coverage of the device. For example, one claim in Land's patent was, any device wherein the development process takes place as a result of or an action of the device or casual user. That is why Kodak did not have a Polaroid type camera for 17 years. It was totally proprietary to Mr. Land.

Source record: 110535

Hi all. You might want to be careful about putting the choke in the negative lead of a full wave configured power supply. If a short, even a momentary one like a flashover were to occur, then almost the full supply voltage would appear across the choke and, therefore the center tap of the transformer. Center taps are often placed near the core NOT anticipating high voltage, and can be punchured in this fashion..73 de Cliff W6HDO

DANGER! putting the choke in the negative lead REDUCES the HV requirement
from roughly twice the operating voltage to roughly the operating voltage.
there is still a very serious dielectric requirement.

>you may be able to find a big filament transformer whose primary winding
> provides sufficient inductance for your application.

high voltage is serious stuff -- do it right!

: program", so common I never heard of it. From the posts I have read thus
: far, apparently our Tax Dollars paid for it's inception and private
: companies are offering it for sale, making it even more proprietary than I
: originally suspected.

OK, Gary. I'm going to try to clarify what I feel is one of the roots
of the mis-understanding here. NEC was developed under government
contract. Mini-Nec is a derivative that is simpler to use (the original
NEC was rather un-ruly). Mini-Nec and NEC2 *are* available for free.
You can get them on the net (Try archie). The user-interface is a rather
crude character-based one.

Several companies have taken the NEC or mini-NEC engine and added features
such as graphic plots and improved operator interfaces. This is the
value added that they charge for! The code that does the numerical
work is *not* proprietary.

As for your lack of knowledge about the availability of NEC, I am
surprised, given that you design antennas! Every Ham-radio publication
has mentioned this software at some point or another, and it has
been mentioned in THIS NEWSGROUP many times.

: In my course of study to upgrade to Advanced Class, I try to find out
: everything I can about the questions posed in the exam. When I tried to
: find out about the "Method of Moments" I initially found nothing about it.

: Until today, I just figured it was the property of the ARRL, now I find many
: different private enterprises have claimed something our tax dollars already
: paid for.

Well you have been looking in the wrong place. The ARRL ANTENNA Book,
like many ARRL publications, is a cookbook. If you want theory, you

better look elsewhere. If you research one of the modern textbooks
on *Electromagnetic Theory*, you should find a discussion on the
method of moments.

: In any case, both of the questions presented in the current question pool
: are directly contrary to the FCCs goal of giving the public the best
: possible service at minimal cost.

Service? Cost? The test isn't a service to you -- it exists to find out
your technical aptitude and knowledge of certain rules.

: There are currently 582 questions in the Advanced question pool.
: Hypothetically, if 1 out of every 10 questions consisted of proprietary type
: information and this information cost you $29.95 to obtain, it would cost
: you well over $1,500.00 just to study for your upgrade.

Are you defining proprietary information to be that information which you
must pay some price to obtain? Certainly if you want to study for an
upgrade, you would need to buy a book at some point?

: Commentary about replies to my original post:
: Donald J. Miller - They don't give it away free either!

You can ftp mini-nec over the net. Use archie to search for it. I know
that there is a directory on netcom.com that contains it. Someone else
reading this newsgroup will certainly know which directory (or another
site).

: Roy Lewallen W7EL - Your two key words were "Brief Description" and
: "Purchased"...Brief Description is not a computer program and
: purchased means to me, proprietary.

So, your definition of proprietary DOES mean you have to shell out a little
cash? I guess I spent those years in college gathering *all kinds* of
proprietary information. I had to buy books for most courses, and the
courses themselves --- well, they weren't free.

Although I don't agree with your definition, I can still prove that the
information regarding M of M is *not*, ahem, PROPRIETARY. Care to
place a wager that I can't make a trip down to my local PUBLIC library
and find some Emag book that talks about it? (I wouldn't take this
bet if I were you!)

In summary:

1) Perhaps they are including questions that are a bit more difficult to
research that before. The study guides probably haven't caught up
with the question pools, and test preparation isn't the cakewalk
that it used to be. Well, perhaps the test is going to start to be
more "real world" -- the student may have to study more than just
one or two resources to master the needed material. If you've
been to college, this should not bother you.

2) NEC is not, repeat NOT proprietary.

3) Yes, you can get versions of NEC for FREE!

4) If you would like to learn more about the method of moments, you can find out more by visiting a good library.

If you had just complained about the M of M information as being hard to find compared to other material, or the fact that you couldn't find reference to it in the ARRL publications, the folks reading this newsgroup would certainly have turned a more sympathetic ear. Rather, your outrageous accusations of the questions being based on proprietary information and if I say so myself, your inflammatory delivery of the same, caused quite a different reaction.

As for myself, I probably would have not replied after my first followup had you not replied to it with your obviously ignorant reaction that mini-nec was not free.

Please try to be a little more exhaustive in your research before you erupt the next time.

> some problems, but were hoping to release it soon.
>
> Has anyone built any of their kits before?
>
> Mark, KE4IOF
>

I built one of the Ten-Tec "T-Kit" 6 meter transverter kits...
Works quite well, uses discrete components (easier,cheaper repairs
if necessary). Includes EVERYTHING...all parts, case, switches,
connectors, wire...
The manual was very comprehensive, Tuning was simple.
Mine worked the first time ! I use it with a TS-50 in the car...
Worked about 50 grids including some rare ones this past spring.
Without hesistation, I recommend it to anyone who already ownes an
HF rig and wants to check out 6 meters. The best $100 I've spent on
the hobby in years !

Regards...
Hugh Duff VA3TO Toronto

Winding-to-case breakdown isn't too critical, as I can mount the
>choke on
>a dielectric support.

From here cannot help with source of chokes. However, the voltage breakdown requirement is considerably reduced by placing the choke in the negative supply lead rather than the usual method where it is wired in the positive side. Achieves the same thing.

Don is absolutely correct. If you're interested, there's a very good but brief description of the method of moments in John Kraus' _Antennas_, second edition. If you're a real glutton for punishment, you can get _Moment Methods in Antennas and Scattering_, edited by R.C. Hansen. It's a collection of papers on the topic. And both MININEC and NEC-2 are public domain. Their manuals can be purchased.

I may be way off base here, but I was under the impression that the main rush toward high drives and GG AB2 amplifiers was when the FCC decided they had to give 'type acceptance' to commercial amps. The 100 watt drive level fit with current transmitters without the need for step attenuators, and it took just a few of the possibilities away from the CB group.

Actually, back when we had to build our own equipment, many a tetrode amp was built to work with a 10 watt exciter. Done a few myself. What I'm trying to point out here, is the prevalence of GG amplifiers was caused by political rather than technical considerations.

: Any ideas would help. I am looking for about 50dB
: of gain or so. More than one device is OK.

: Thanks

: Steve Muther WF6R

Steve,
Although the MC1350 and MC1590 have been suggested, I myself prefer
the CA3028B differential amplifier when it comes to a good linear AGC amp-
lifier for 455 KHz or 10.7 MHz. You have to add matching circuitry to use
them above this range. They have about 30 dB of gain as a single-ended
amplifier (aka cascode), and around 50 dB of AGC range. Newark sells them
for around $3.00 each, but they can be obtained for as little as $1.80 for
the SOIC version.

I'm not too crazy about using mega-transistor IC's for RF
work. The characteristics and noise of these devices make me cringe with
fear. A single bipolar device will usually outperform anything except
a good Nuvistor tube.

I know I'm going to catch hell for this. I just know it.

Joe-
I believe what you need is a balun, which is used for matching
unbalanced 50 ohm coax to 'balanced' 300 ohm twinlead or the like.
Look in the October issue of Electronics Now (was Radio Electronics).
This contained an article that described the designing and building
of baluns.

Hope this helps you out!

>K0UYH
>
Hello Karyn(?),

Actually I think it was the ready availability of 50 to 100 watt exciters
and availability of inexpensive tubes better suited for grounded grid that
caused the change.

The CB rules came out long after gg amplifiers were popular.

The most popular amp designs were the most simple and least expensive
designs in the long run, and a GG single ended triode is by far less
costly and much more simple than any type of tetrode amplifier design. It
was a course of natural evolution.

The gg amp is less costly to build and maintain than a grid driven tetrode
or pentode in most applications.

4333. Patch Antennas -- References??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-21 00:00:00 UTC
From: rst-engr@oro.net
Message-ID: <43s8o4$cuu@hg.oro.net>
Source record: 110542
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

In the October '95 issue of QST, Hal Ward (W1GE) wrote an article on a GPS patch antenna. One of the references he used to design the antenna was a book by David Pozar titled "Antenna Design Using Personal Computers". Hal also noted that the book was published by Artech House in '85 and is out of print.

It is also out of library. My library did a data search and came up empty. Does anybody know either (a) where I can get my hands on a copy of this book even if only for a day or (b) another good reference text for patch antennas. Neither Jasik nor Hamsher (my two antenna bibles) make any reference to a "patch" antenna.

You can post here or email me, whichever suits your fancy. BTW, I will obviously be willing to pay copy and/or postage costs for any of this information.

Thanks for your help, gang.

I dont know of a free source, but one book I have is:

SPICE - A guide to Circuit Simulation & Analysis Using PSpice, by P. W. Tuinenga,
Prentice Hall, 1988. Cost #25 at some time between 1988 and now.

Cant say how good/bad it is, since I've only glanced at the first few pages, but
other in the department think its okay.

> there is still a very serious dielectric requirement.

True, unless some level of standard safety precautions are followed.

Maybe I should have qualified that the builder needs to include a low-impedance, low-resistance path to ground, to allow for current metering as well as to limit the potential on the (negative) return line.

The ARRL standard practice is to provide two paralleled power resistors of approx 50 to 100 ohms from the return line to a proper chassis ground. This will keep the return from swinging more than a few tens of volts off ground and will sink enough current to blow fuses in a hurry if the voltage does go too far from normal. (Yeahyeah, I know the relative value of ARRL technical information.)

I made the assumption that since the builder is asking for parts here, he's doing this project on the cheap and knows what he's doing, safety-wise and design-wise.

If he's doing this with no prior knowledge of the art, he doesn't need filter chokes, he needs life insurance.

Isolated, full floating B+ and return were not in the design specs the builder provided.

Jim N6OTQ

BTW, I just got flamed somewhere else for volunteering information. I'll grant that I don't know everything, but I feel that what I do know is generally of value and is more information than the requestor had before, and hence is useful. I shouldn't have to cover my you-know-what against everybody's trivial "yes, BUT" objection relating to some off-the-wall case that occurs once in a blue moon. I've offered simple information that I felt was relevant to the scale of the problem described, and hoped that others would add to this information, not trash me for opening my mouth.

There's absolutely no doubt in my mind that if I never posted again, a lot of information that NEEDS to be shared would be lost, to the detriment of a lot of hams. potential hams, and electronics hobbyists (yes, and to newbies in a lot of other fields and hobbies). Punish me for sharing? Great idea. I'll lurk or leave. And so will a whole lot of others who get slammed for offering info GRATIS, leaving the few of you who are so convinced you know everything here to bicker over the tediously trivial.

Have a nice day.

Of course if you're called to the 50KW transmitter to repair a blown final
amplifier tube it helps to have some basic rework skills, especially when
a moth sneaks into the cavity as you are putting it back together after
replacing the final amplifier tube. Such a thing tends to bring the final
down again REAL fast. And since nobody has any replacement chimneys to
replace the one with carbon scoring you get out a Dremel (tm) tool and carve
away the scoring and pray it still works. (This happened to a friend of mine
a couple/three years ago. Wotta mess!)

From: Ian G3SEK <G3SEK@ifwtech.demon.co.uk>
Message-ID: <157636804wnr@ifwtech.demon.co.uk>
Source record: 110555

In article: <43pmqe$qme@news1.inlink.com> raiar@inlink.com (Gary V. Deutschmann, Sr.) writes:

: As an antenna designer myself, I was surprised that the question first
: indicated that the program in question was a "commonly used computer
: program", so common I never heard of it.

If the questions had asked about "NEC, MININEC and related computer programs", would that have helped? Because that's all they mean by "Method of Moments".

I truly can't believe that anyone claiming to be an antenna designer is unaware of these programs, or doesn't already use them intensively.

(On the other hand, if you're the kind of person who never reads page 1 of the manual but jumps straight into the interesting stuff, then you might have missed the academic information that all these programs use the method of Moments :-)

These programs are the biggest single development in antenna design for decades - or maybe even the biggest development ever. No holder of a recent Amateur Extra ticket should be wandering around in total ignorance of their existance or importance.

: From the posts I have read thus
: far, apparently our Tax Dollars paid for it's inception and private
: companies are offering it for sale, making it even more proprietary than I
: originally suspected.

You can download free, fully working versions of NEC and MININEC, and even the source code, from many academic ftp sites. You can order full printed reports from NTIS for a few dollars more. There's even an amateur-written beginner's FAQ for MININEC.

What you'll find is that both programs are very powerful, but competely user-oblivious. People like W7EL and K6STI have put thousands of hours into improving the user interface, adding plot routines, streamlining the calcuations and taking some bugs out of the original code. In other words, they have turned NEC and MININEC into usable tools.

When you buy EZ-NEC for example, you're paying for all the proprietary enhancements that make it "EZ" to use: you're not being asked to pay for any of the original public-domain NEC code.

If you don't choose to buy an enhanced (read "usable") version, you're completely at liberty to struggle on with NEC or MININEC -

or write your own enhancements.

Coming back to the exam question: OK, so you got a stupid answer
from whoever you chose to ask at ARRL - but that doesn't change any
of the above.

Now can someone please post a word-for-word copy of the questions
and answers, so we can see what all the fuss was about?

Don't be bashful - the questions aren't proprietary :-)

: Hypothetically, if 1 out of every 10 questions consisted of proprietary type
: information and this information cost you $29.95 to obtain, it would cost
: you well over $1,500.00 just to study for your upgrade.

Aw, c'mon Gary! Something about these two questions has "pushed
one of your buttons" and provoked a fury that is totally out of
proportion. We all have these buttons, and some of them are marked
"Amateur Radio". (Me too: I'll confess to having hurled RSGB's Radio
Communication Handbook across the room :-)

It's time to press "Reset".

If your system is getting a FULL news feed that means 400MB/day. No system has infinate storage, so yes, old matterial will be deleted. How long stuff is kept varies from site to site, but 1 week is a common retention time (though I have seen sites that retain stuff for a month, and others that only hold onto stuff for two days). If your concerned about how long matterial stays at your site, talk to your system admin (and maybe offer to buy him/her a few GB of storage ... :-)).

Gee, depends on which manual. As others have said, you can get one of the many books that folk have written about Spice. I recently got Rashid, "Spice for Circuits and Electronics Using PSpice," second edition, Prentice Hall. Seems OK. Before that, I used just the Berkeley manual which you used to be able to get via ftp from the UC Berkeley site; I don't recall its exact name right now. It's available at least in postscript format, which produces a fairly nice printout on a postscript laser printer. It's for Berkeley Spice 3. It won't tell you very much about the hows and whys and troubleshooting, but it tells you what models are built in and what the format is for them.

I am working on a microprocessor based device for a medical application. What I need is a simple circuit to detect proximity of the device to the human body -- in other words, a binary (go/no go) indication if the device is on the body or has been removed.

I am thinking in terms of two small metal plates (which could actually be pads on the circuit board itself) that constitute the plates of a large air-capacitor. In theory, I think, an oscillator could be adjusted to break into oscillation when the value of the "capacitor" changes due to the proximity of human flesh.

Another possibility would be to excite one of the plates with an oscillator. The other plate would be connected to a rectifier and comparitor. The comparitor would be triggered when rf coupling between the plates increased (due to the presence of human flesh).

I can kluge something together on a breadboard that will do all this. But what I need is an *optimum* design that can meet the following specifications:

* First, the lower the parts count, the better.
* The more generic the parts, the better (for future production reasons).
* As low a current consumption as possible (device is battery powered)
* 3 volt supply max.
* Must provide a binary (on/off) output that can be connected to an i/o pin of my microcontroller (a PIC 16C74)
* For power conservation reasons, ciruitry should only "turn on" when enabled by a microcontroller i/o pin. (0 or 3 volts).

If you have tackled a similar problem, your input would be greatly appreciated. Please E-mail responses directly to me. Thanks in advance.

Hi Jim,

Let me add a bit to this. there have been some very good posts here. I'm pleased as can be to read some of the nice information, including yours. Let me add a bit to yours post if you don't mind.

In article <43ruuc$mu5@unisql.unisql.com>, Jim Strohm <jstrohm@blazer> writes:

>Maybe I should have qualified that the builder needs to include a
>low-impedance,
>low-resistance path to ground, to allow for current metering as well as
to
>limit the potential on the (negative) return line.

That should always be done in a suppy if the chassis operates close to the negative rail in potential. On rare occasions it can not be done (like a tetrode with grounded screen).

>
>The ARRL standard practice is to provide two paralleled power resistors
of
>approx 50 to 100 ohms from the return line to a proper chassis ground.
This

ground
>and will sink enough current to blow fuses in a hurry if the voltage does

>go too far from normal. (Yeahyeah, I know the relative value of ARRL
>technical information.)
>

I don't think that's good advice to follow. No, let me re-phrase that....it's plain unvarnished ignorance for a technical publication to reccomend that method of rail protection. Let me explain why.

1.) During a HV fault (and that is a common occurrence) the filter capacitance in the supply can release many hundreds of amperes of current, and the 50 ohm resistance will still allow the negative HV rail to rise nearly to full supply voltage.

2.) During the fault, the resistors will be subjected to huge overloads. If common wire wound, metal film, or carbon resistors are used (instead of the proper expensive and rare surge rated resistors) the components depended on for protection may fail.

3.) Even during normal supply operation, the negative rail can float to dangerious voltages. As little as one ampere can pull the negative rail to 50 or 100 volts if a negative rail connection fails or is not attached.

I always use a diode network (with heavy diodes) to clamp the negative rail to the chassis, as well as a liberal sprinkling of 50 volt rated by-pass capacitors. The normal failure mode of these components is shorted, not open. So even in the event of a huge fault current between the rail and ground the supply rail remains clamped. Additionally I use a HV rated fuse and/or high surge current and voltage rated resistor in the positive lead near the capacitor to output connection (the bleeder remains directly across the capacitor).

>I made the assumption that since the builder is asking for parts

>filter chokes, he needs life insurance.
>
>Isolated, full floating B+ and return were not in the design specs the
>builder
>provided.
>

Don't forget the choke is a high impedance, so it can have an appreciable amount of voltage on the ungrounded lead, even if the negative rail is at chassis ground.

A second more severe problem can occur with chokes, they can act like an induction coil and "kick back" several times the normal operating voltage. I usually include a spark gap across large chokes to limit the flyback voltage to reasonable values.

Lastly, let me tell a true story that may save lives. In the late 60's I built a 6000 volt supplyn (for a pair of 4-1000A's) using very good components. I tried to use a resonant choke filter circuit as suggested in the Bill Orr Handbook (commonly called the "West Coast Handbook".

Every time I closed the line switch my PA tubes would arc from the anodes to the grids, and the breaker would open. I connected a HV meter to the supply positive terminal through 40 kV insulation wire, stood back on a rubber mat, and turned the supply on with the RF deck HV lead unhooked.

The surge actually blew through the new HV wire and the wi

I tried to send a reply to this by e-mail, but it bounced. Since it
may be of interest to some readers, I am posting the reply.

>Things to consider:
>additional filter caps may be cheaper than a filter choke, and will definitely
> weigh less

But a capacitor input filter puts much more stress (in the form of RMS
current) on the rectifiers, transformer, and power line. There's a
good set of reasons why high power equipment almost universally uses
choke input filtering. My experience is that the most reliable
single phase high power supplies use a bridge rectifier and choke
input filtering.

>if you put the filter choke in the negative leg, you remove the requirement
> for HV protection and reduce/eliminate the need for a dielectric
standoff

You reduce the requirement some, but you don't eliminate it. Assuming
a single-phase system, there are times when the output voltage from the
trasnformer is zero, and the choke is busy supplying the missing
voltage. At those times, the input end of the choke has the peak
secondary voltage on it. At other times, it has essentially zero
volts on it.

>you may be able to find a big filament transformer whose primary winding
> provides sufficient inductance for your application.

I have tried this, and have never found a transformer which didn't
have its inductance collapse dramatically in the presence of DC
current. This makes sense, since transformers don't incorporate
an air gap in the magnetic path.

If you really need high power, three phase is the way to go.
Unfortunately, the power companies aren't willing to furnish most
of us with it at home.

From: w8jitom@aol.com
Message-ID: <43sjuh$ghc@newsbf02.news.aol.com>
Source record: 110570

What a weird scramble? My text was little garbled. So let me finish.

The supply arced through the insulation and blew the wire in two, and the wire pasted itself to my wrist. I received 1st, 2nd and 3rd degree burns from that experience.
The resonant choke filter suggested in the book almost killed me! The rubber mat and grounded panel certainly saved my life.

Since then I include spark gaps or other clamping across chokes. As near as I could figure, when the choke hit resonance at turn on it must have "rung" a bit. The peak voltage must have built up to many kilovolts of surge causing the tubes to arc, and when they were removed the test lead became the breakdown point.

Weird things can happen, so I am more cautious now.

Fair enough, though I suspect FAR Circuits would be happy
to make and sell the boards.

>I'm still waiting for an Internet PCB layout standard to
>evolve. In fact, few hams other than myself seem to be
>distributing Net compatible layouts in *any* form. I'm
>currently generating Postscript files using HiWire, a
>CAD program by Wintek, but suspect I ought to switch over
>to Autocad to gain the flexibility of generating things
>like properly dimensioned rat race microwave mixers.

Yeah, I'd prefer the Autocad format. I've got that and it
talks to my plotters. I don't have Postscript and have to
kludge that through ghostscript to print it on the old
HP Laser.

Maybe we should start some discussion on this topic. (I've
added .homebrew to the distribution.)

I'd like to see us standardize on a schematic distribution
format, a netlist format, and a mechanical drawing format.
Then form a rec.radio.amateur.CAD group where we could
post such things, as well as Radio Designer and Spice
files, Mathcad worksheets, etc. Since many of the CAD tools
can handle several formats, and there are utilities to convert
others, perhaps we should start with a survey of what tools
the majority of us interested in this have in common and see
if there are common formats we all share. I'll kick it off.

Mechanical:
1) Autocad
2) Generic CADD
3) CD-CAD

Schematic Capture:
1) Orcad
2) Supercad
3) MicroSim Schematic Editor

PC layout:
1) PCBoards

Routers:
1) PCRoute

Circuit Simulators:
1) ARRL Radio Designer
2) PSpice

Paint programs and image viewers:
1) MS Paintbrush
2) Visual Image

Math tools:
1) Mathcad

That should do for a start. I'll try to keep a running tabulation
on followups and see what we have available to us.

Gary

It does, or at least the one I have does. It does a kind of differential measurement, as I recall, between a fixed cap and the variable one with printed circuit board plates. The plates aren't large. The caps are the timing caps in two sections of a dual monostable, 74HC123 or some such. For this application, it should be easy to just use a fixed cap on one side and the plates on the other. Trigger both at the same time. If the variable times out before the fixed, no person present. If the variable times out later, then there's a person (or other conductive or high dielectric constant object) nearby.

NEC was developed at public expense, and is available, including source code, for free, on the net and elsewhere. NEC isn't very user friendly, however, and several companies package the NEC engine in a friendly user interface and sell the result. You're paying for "user friendly" not for NEC. If you can live without point and click, you can run good old mini-NEC for only the cost of downloading the bits. There's nothing even remotely proprietary about it.

Since NEC seems to be so widely used among professional antenna designers, and examples of NEC plots so widely published in professional papers, it's *very* surprising you, as a self-proclaimed antenna designer, didn't already know about it. And that's all the exam question, A9B09, is trying to determine, your knowledge of the *existance* of a common antenna design tool. The other question is trying to determine if you understand a very common numerical methods technique. To the computer literate, this is akin to asking how do we arrive at 2+2=4 (though honestly the latter is a tougher question to answer properly).

>Until today, I just figured it was the property of the ARRL, now I find many
>different private enterprises have claimed something our tax dollars already
>paid for.

You'd have had better luck finding out about the method of moments
in a numerical methods textbook. It's a classic algorithm for doing
piecewise numerical integration, a form of the Newton-Cotes method.
It's a widely used technique in mechanical engineering, as well as
in electromagnetic modeling. It's not specific to antennas.

As an aside, the ARRL antenna books are *cookbooks*, you didn't really
expect to find anything to do with *theory* in there did you? (This is
a really serious failing, and one that I've railed about before. With
antennas and EM radiation such an important part of amateur radio, the
ARRL publishes *nothing* that explains the theory of how antennas generate
EM fields. Sure, they devote an entire chapter to transmission line
calculations in the Handbook, but when it comes to antennas they are
merely descriptive and only offer cookbook recipes for a limited subset
of radiators without a word of explanation of *why* they work.)

>In any case, both of the questions presented in the current question pool
>are directly contrary to the FCCs goal of giving the public the best
>possible service at minimal cost.

Service? The tests are to determine your competency in the field.
If you aren't even aware of a widely used tool's existance, the
test seems to be doing its job of weeding out the incompetent, or
more politely, of serving to lead you to discover valuable and
widely used techniques you were not yet aware existed.

>There are currently 582 questions in the Advanced question pool.
>Hypothetically, if 1 out of every 10 questions consisted of proprietary type
>information and this information cost you $29.95 to obtain, it would cost
>you well over $1,500.00 just to study for your upgrade.

Oh, please. In any educational setting you expect to pay for the
information and tools you are gaining. You buy books, pens, paper,
calculating tools, pay tuition, etc. That doesn't make the knowledge
you gain proprietary. A computer program is no different than a
slide rule, it's just a calculating tool, and you don't *really*
expect such tools to be *free* do you? In this case, NEC really
is free, in the sense that it was already paid for by all our taxes,
but that's really an exception. Should the exam not have questions
about the tools commonly used in the field? Remember, you don't
have to own a copy of NEC to answer the question. All is expected
is that you be aware that it *exists* and is in common use by
antenna designers. That's no different than a question that asks
what instrument do you use to measure VSWR. You don't need to go out
and buy a reflectometer to answer the question.

If this device will consist of two electrodes in contact with the skin,
then the simplest solution is to build the equivalent of a megohmmeter.
The output should be fed to a CMOS comparator, then to your controller.

Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

[This post lists all the information I'm looking for. You'll only have to look at this once in a while from now until the FAQ is ready - N1OOQ]

The Land Mobile Radio FAQ is now under way... I need your support!

What is it?

A listing of those surplus police and taxicab radios from the various manufacturers, how to identify them, what band they're on, how easy it is to tweak them into the ham bands, average price used, etc., all in one file for your flea market shopping convenience!

What it's not is a mod manual. You won't find out HOW to do the mods in the FAQ. That's up to you. You will find out where to get the manufacturer's manuals, most of which have detailed tuning procedures. Some of the radios can only be programmed by the manufacturer, and/or by using the manufacturer's proprietary software. Such details will be in the FAQ.

I'd like to include any and all mobile or handheld radios aimed at the commercial or public service market. Many of these out-perform the imported synthesized units by a long shot, are cheaper, and make great ham rigs! Let's put these great radios back to work and on the air!

I NEED YOUR INPUT TO MAKE THIS A REALITY!

You don't need to mail me manuals or anything like that, unless you WANT to. All I ask is a few bits of data for any of these radios you or your friends may have worked on in the past. If you've put one on the air, you've had to answer these questions, so fill 'em out and send 'em in!

Model? Manufacturer, model name (like Mastr II, Syntor, Delta, etc.), model number

Band? These radios are usually made for use in a specific band of frequencies, like 30-50 MHz, 150-170 MHz, 450-470 MHz, etc.

Freq control? Crystal, synthesized/ROM programmed, synthesized/microprocessor programmed

Average price? What did you pay? What prices did you see when shopping? New or used?

Manual price? How much did the manual cost?

Mod difficulty? How hard was it to get it tuned to ham band? Easy: re-crystal, tweak a few tuning screws

Difficult: program a new ROM, swap a few parts
Extremely difficult: Major modification and re-design
of some circuits, you must pay
authorized technician to use
manufacturer's software

How to indentify? What details do you need to know to tell these radios
apart? Does the serial number tell you anything? Does
the Model number? Are there physical differences?
This is the stuff you need to know when sorting
through the radios at the flea markets. This
information is usually in the manufacturer's manuals
in great detail.

I will re-post this notice about every couple of weeks for a while, until the
FAQ is somewhat filled out.

My net address is: randolph@est.enet.dec.com
All information, network pointers, periodical references, anything, is
appreciated, and thanks in advance!

-Tom R. N1OOQ randolph@est.enet.dec.com

snip....snip
Good idea Gary, but I suspect that we'll run into a pretty wide
variety of tools that interface poorly, if at all. But for my part:

Mechanical CAD
TurboCAD - by IMSI
Generic CAD - not currently using

Schematic Capture
PCAD

PCB Layout & Routing
PCAD

Circuit Simulation
Intusoft Spice

Math tools
Mathcad - but not very experience with it

Logic development tools
CUPL - normal PALs
MAX+PLUS - Altera logic

> on followups and see what we have available to us.

Gee. With the possible exception of Generic CADD none of these are Macintosh compatible. I vote for a narrower scope of "standard", simple Postscript. A Postscript printer is much less expensive than Autocad (assuming you actually pay for Autocad) and any kind of "standardization" of file formats dictates need for each and every one of the programs.

Or maybe the standard should be based on free tools and operating systems such as Linux and/or FreeBSD? What? Not enough tools there? Then making those tools would be the first step.

While many software packages claim to support other's formats I have never seen perfect support for any but pure text and often even that is problematic (does "pure text" use <CR><LF>, <LF>, or <CR> to terminate lines?) End of line problems are pretty easy to solve. Gary discounts Ghostscript as he has not been satisfied with its results translating Postscript. Can we expect DXF translaters to do any better?

Postscript is not perfectly portable between printers but Adobe has done a great job making sure genuine Postscript printers are very compatible.

For netlists any ASCII format is fine. If I like what I see in a Postscript schematic I can find a way to translate an ASCII netlist into a form suitable for my PCB tools. Any respectable print shop could print PCB artwork on film from Postscript. Often I've found this less expensive than Gerber at the same shop possibly because there is no manual entry of aperatures. As long as they don't use a Linotype 100 its just dandy.

If it is for medical purposes. Unless you are already making electrical connections to the patient (in which case I hope you know what you are doing!!), try something that make no electrical connection to the patient. An LED modulated at a few kHz, with the reflected light falling on a photodetector would be my approach. Capactive methods might also be practical. Insulated microswitch ???

I would definately avoid the electrical conductivity method.

There is also a medical physics newsgroup: sci.med.physics, which will be of more use than this one. I hate to say this but I will. As radio amateurs we often do things we should not -> Overrun components, use surplus components etc. You need a different approach for medical equipment!

Source record: 110485

Tom is SOOOO right!

: 1.) During a HV fault (and that is a common occurrence) the filter
: capacitance in the supply can release many hundreds of amperes of current,
: and the 50 ohm resistance will still allow the negative HV rail to rise
: nearly to full supply voltage.
:
: 2.) During the fault, the resistors will be subjected to huge overloads.
: If common wire wound, metal film, or carbon resistors are used (instead of
: the proper expensive and rare surge rated resistors) the components
: depended on for protection may fail.
:
: 3.) Even during normal supply operation, the negative rail can float to
: dangerious voltages. As little as one ampere can pull the negative rail to
: 50 or 100 volts if a negative rail connection fails or is not attached.
:
: I always use a diode network (with heavy diodes) to clamp the negative
: rail to the chassis, as well as a liberal sprinkling of 50 volt rated
: by-pass capacitors. The normal failure mode of these components is
: shorted, not open. So even in the event of a huge fault current between
: the rail and ground the supply rail remains clamped. Additionally I use a
: HV rated fuse and/or high surge current and voltage rated resistor in the
: positive lead near the capacitor to output connection (the bleeder remains
: directly across the capacitor).

What many designers don't appreciate is that in the event of a short from B+ to chassis (like when you switch on without disabling the top-cover safety switch) the short-circuit current will flow UP FROM GROUND to the B- rail. As Tom says, in the absence of any built-in precautions this can hoist the B- rail way above ground. It will probably vaporize meter shunts, meters and various other forms of delicate electronics connected in the region between B- and ground.

There's a dual approach to safety here.

First, Eimac and other tube manufacturers recommend a high-wattage resistor in the B+ lead. This is not intended as a fuse, but as a current limiter. About 25R per kV of B+ will limit the maximum possible current to 40A. This will help greatly to protect the tube in the event of an arc-over, and also protects the region around the B- rail. The other advantage of this B+ resistor is that it gives you a definite maximum current to design for (the actual maximum current might be less, but it can't possibly be more).

In the B- rail, the main short-circuit protection should be a DIODE (as Tom says). Yes there are resistors there too, but the diode pointing UP FROM GROUND is the real line of defence to prevent the B- rail from flying away above ground.

If the maximum possible current is 40A, why not use a protection diode that is rated for 40A continuous? After all, they don't cost much and a lot of collateral damage risk is riding on that component. The cheapest source is a 40A potted bridge rectifier: connect from corner to corner and you have two diodes in parallel, back-to-back with two more. (The reverse diode, pointing down from B- to ground is under much less stress.)

The meter shunt resistor (for grid current in the case of a GG amplifier) is connected in parallel with this protection diode. To prevent the diode from affecting the meter readings, the voltage drop across the shunt must be much less than 0.5V.

Obviously you can connect other high-wattage "safety" resistors between B- and ground if you want to, but the DIODE is the real safety component.

To repeat: over-rate everything, because come hell or high voltage the B+ resistor and the safety diode have got to hang in there for as long as it takes the fuses to blow!

Here's a quick poll of the 1995 ARRL Handbook.

Power Supplies chapter: no mention of B- protection. The two HV supply projects both feature 10R 25W resistors from B- to ground and 50R 50W resistors in the B+. Not bad... but only if there's some effective B- protection in the PA.

1500W HF amp and PSU: 15R 20W from B- to ground in PSU, 10R 20W in B+. The amp has another 10R 25W in series with B+ and unusually 25R 10W in series with the B-. That's a total of 45R to limit the prospective B+ short-circuit current to 100A, give or take. But the short-circuit protection diode (D104) in the PA is "1A, 100PIV, such as 1N4002". And if that diode fails, everything goes through the grid-current meter.

8877 amp and PSU: 10R 25W from PSU B- to ground, 10R 25W in PSU B+. Another 25R 25W in the PA B+ and - yes! - a 1N4007 to "protect" the B- rail and the meters from the effects of a B+ short!

Get the picture? All the other designs are the same. They all use a 1N400x because that's what the guy before used. (OK, so a 1N400x has a much higher surge-current rating than its continuous rating of 1A. But don't try to tell us that's why they aren't using anything larger.)

On a related topic, why do US designs always seem to use the single-pole Millen HV connectors, and not a coaxial HV type that

automatically provides a ground return as well? The idea of making
it physically possible to connect the B+ and forget the separate
ground/B- wire scares the hell out of me!

Ian (G3SEK) make some useful point about HT supplies. ...

> On a related topic, why do US designs always seem to use the
> single-pole Millen HV connectors, and not a coaxial HV type that
> automatically provides a ground return as well? The idea of making
> it physically possible to connect the B+ and forget the separate
> ground/B- wire scares the hell out of me!

I could not agree more with the last point, but would add this. I've seen it advocated to use the PET 100 series of coaxial connectors. I've used these and never had any problems on a 2kV pair of 4CX250B's. I have one on a pair of 4CX1000A's too (at 3kV) and never had a problem on that either.

However, I've since discovered another type of connector, which looks better. My worry with the PET 100's is that if you pick the connnector up with it *unmated* with a few kV on it, it looks to me as if you might just be able to get a belt. Unlikely I admit, but not totally impossible. The better connectors (in my opinion) are:

SHV=Safe High Voltage. Rated 5kV (3.5kV RMS) at 10A. Note the 5kV is valid for mated or unmated
connectors. These are excellent. They look a bit like BNC's, but the PTFE insulator sticks out *way beyond* the metal parts of the connector, making it impossible to get a shock even if you tried.

Another type, which I'm not so keen on, is the MHV (Minature High Voltage). These are no smaller, and again are rated at 5kV 10A. However, the Suhner catalogue says these give less protection in the unmated condition than the SHV's. The MHV's, also known as an H4, look even more like BNC's.

None of these connectors are cheap. Suhner (Tel: 01869-244676 in the UK) have (last time I ordered) a #50 minimum order and seem to take ages to deliver, but I would personally not build another high voltage amp with PET 100's. PET 100's are not cheap either, so the differential between these is probably well worth the extra cost.

If you need over 5kV, I've no idea what is best. I would be interested to hear of anything suitable that people know of - not that I have any tubes needing > 5kV!

Hmm, looking through my shelf:

Antennas by Kraus, 2nd edition has an entire section on the
moment method (p. 359-408), though that section is actually by Edward H.
Newman (so says the title page).

The _Antenna_Engineering_Handbook_ by Johnson (used to be Jasik), 3rd
edition has a small blurb on the moment method on pages 37-9,10.

_Advanced_Engineering_Electromagnetics_ by Balanis (1st edition I guess,
(C) 1989) has a large section on the moment method (p. 670-731). I
picked this one up cheap at a flea, just because of its discussion of
the MofM.

Better update those texts, Tom. :-)

The method of moments is a numerical technique of figuring out the
unknown current distribution on some structure (like an antenna).

The following didn't make it throught the text editor:

Unnecessary series resistance should NEVER be placed in *series* with the negative (near ground potential) lead of a HV supply for obvious safety reasons.

The non-surge rated limiting resistor are not speced to handle the operating voltage.
And what good does a 1 A fuse do in the cathode??? Fuses are too slow and unpredictable for serious protection, although they can prevent fires!

>8877 amp and PSU: 10R 25W from PSU B- to ground, 10R 25W in

Well the *normal* failure mode is shorted Ian, so I understand the 1N400x. But the unreliability indicated by the word "normal" causes me to think adding secondary failsafe components like LV rated bypass caps is worthwhile. Nothing wrong with a bigger diode like you suggest, except let's not put all our eggs in one basket here. Let's tack in a few 5 penny parts for extra safety.

>

Because cost outweighs safety. On this side of the pond we prefer a little excitement, such as pulling the unprotected ground lead while letting the cat sleep on the chassis near our feet. :-) That's why we connect the power line center-tap to chassis here also!

I would like to build an antenna switch for 2m and 70cm. I was wondering if in need to special toggle switch or can I use the Radio Shack variety SPDT toggle switch? Also, should the wiring inside the box be shielded coax also?

Thanks,
Kory

I'd recommend avoiding switches, particularly at 70cm. If you've seen some of the discussion about how poor UHF-series connectors are, you will realize that it's very difficult to keep SWR low through a mechanical switch that isn't designed very carefully for the line impedance. Isolation to the "OFF" port will probably be poor, too, in case that matters. Basically you need to consider every centimeter of the path as transmission line if you want good performance.

If you don't need to switch very quickly, I'd recommend you just use BNC cables. You can bring things out to a "patch panel" if it makes it more convenient, or you can use a BNC f-f "barrel" connector to splice two BNC terminated cables.

If you really want to switch, I'd suggest you get a relay rated for use at 70cm. But these are usually kind of expensive, and then you have to have power to drive the coil.

If you absolutely _insist_ on using a mechanical switch, you might use a slide switch. There was an article about building a switched attenuator in QST around a year ago that described how to arrange the switch mechanically so it maintained a reasonably constant impedance. And I think in the RSGB VHF-UHF manual there's a description of a build-it-yourself relay that could instead be driven mechanically, if you are inclined to do some serious mechanical work.

Sorry things aren't simpler at UHF, but that's the way it is.

Hi guys...Your comments on the antenna switch was good. The slide switch idea certainly is valid but the power level possible is small. I think the article to which you refer was in QEX rather than QST. 73 Cliff W6HDO

Philips specifies the noise figure at 5dB typ. at 45 MHz.
This is based on an input impedance of 1.5K resistive, 3pF capacitance.
The conversion gain is min 14dB at 45 MHz.
And the output impedance is 1.5K balanced, resistive.

Thanks,

But I still need the noise resistance for the inputs and I dont know if the impedance is the same as noise resistance. I think i can calculate backwards and get noise power, but I don't know how to get the noise voltage or noise current to calculate noise resistance.

<G3SEK@ifwtech.demon.co.uk> writes:

Hi Ian,

Interesting what you pointed out. I never looked at those articles before.
Now that I have, I see why you are concerned. Let me add a few comments of
my own.

>
>Here's a quick poll of the 1995 ARRL Handbook.
>
>Power Supplies chapter: no mention of B- protection. The two
>HV supply projects both feature 10R 25W resistors from B- to
>ground and 50R 50W resistors in the B+. Not bad... but only
>if there's some effective B- protection in the PA.
>

I take it you mean page 13.32.

My comments are:
R207 is too low in value. 10 ohms only limits the current to 300 amperes,
and not only that...the resistor is not speced to be the proper surge
rated HV type resistor. The resistor may explode or arc across the
internal winding and offer little or no resistance at all to a HV
overload.

No HV B- rail protection. R204 will NOT clamp the negative rail in the
event of an open B- return. If drive is applied to the tubes the B- rail
can only go to 12 volts or so, but if a fault condition occurs and none of
the non-high voltage rated resistors arc internally the - supply rail can
fly up to 1800 volts!

Then how about the 120V blowers returned to the *chassis* instead of the
power line neutral or just being placed across the filament transformer
primary?? What about one side of the filament transformer primary being
grounded to the chassis in the RF deck?? If we're worried about HV if a
ground lead breaks, we should also worry because the whole RF deck chassis
can reach 120 Vac from the unnecessary line voltage "neutral" ground
connections to the chassis.

Wow! A switch in the HV secondary winding!! Lord protect us!

And the builder is not duly cautioned to the hazzards if the shaft is not
securely grounded! The thing shouldn't be in the secondary at all. The
entire text is "S3 is a high-voltage switch with large contacts and
ceramic insulation used to select among the taps." Not enough caution or

care on this item alone.

Now here's where the low voltage design trouble begins..page 13.34 Control circuitry

The exciter is subjected to the full discharge current of a 4.7 MFd cap (C116) charged to 1.5 volts (no current limiting) every time the relay closes. The circuit depends on the internal resistance of C116, the wiring, and D116 to limit exciter contact closure current. The little reed relay in the exciter probably says ouch, and for no reason at all! This overcomplicated sequencing and control circuit now connects to both antenna relays in parallel, so there IS NO SEQUENCING!! The only thing sequenced is the LC voltage, and it is sequenced the wrong way!!!!!

The grid trip depends on the current gain of a 2N2222 (instead of a $.39 comparator) to fire a relay. Not too precise.

I see your point Ian. Lot's of parts that don't do anything. It does look like they were put there just because someone saw them used elsewhere.

>1500W HF amp and PSU: 15R 20W from B- to ground in PSU,
>10R 20W in B+. The amp has another 10R 25W in series with B+
>and unusually 25R 10W in series with the B-. That's a total
>of 45R to limit the prospective B+ short-circuit current to
>100A, give or take. But the short-circuit protection diode
>(D104) in the PA is "1A, 100PIV, such as 1N4002". And if that
>diode fails, everything goes through the grid-current meter.
>

Good point again Ian. But please add this...

NO RF bypassing on the negative rail in the power supply. It would help with safety if the bypass caps were 25 or 50 volt rated devices. The bypass caps in the RF deck negative rail should be LV types (25-50 V) so they fail shorted to protect the operator.

Unnecessary series resistance should NEVER be placed in *series* with the negative (near ground potential) lead of a HV supply for obvious safety reasons.

The non-surge rated limiting resistor are not speced to handle the operating voltage.
And what good d

In the Third Edition of Jasik (edited by R. C. Johnson), patch antennas
are discussed in chapter 7, Robert E. Munson, "Microstrip Antennas."

The second edition of Kraus also has a section on patch antennas.

If all else fails, I do have a copy of the book you are looking for.
Pretty rudimentary stuff, and a bunch of BASIC programs in that book.
You are far better off with Jasik and Kraus; believe me.

Mark me down for Generic Cadd - This also will handle many
AutoCad files as well.

I would cast a vote for the most usable for the general amateur
homebrewing population. Maybe HPGL files are more generic.
There are several inexpensive Cadd programs out there that will
handle them. I can foresee many users that simply want to print
schematics, and an investment in a $400+ Cad program seems a bit
expensive just for that purpose.

One rather significant problem Gary didn't mention is the sync capabilities of a given monitor. Some multisync monitors can't syncronize to NTSC horizontal rates properly; for example, the lowest frequency an NEC MultiSync 3FGe monitor can sync to is 31 kHz, which is well above the 15.734... kHz frequency used in NTSC video. You'll need to determine if your monitor can operate successfully @ NTSC horizontal rates, otherwise some modification to the monitor itself may be necessary.

I don't know what you're trying to do, but you may be better off trying to find a good used TV w/ a baseband video input rather than trying to kludge up a PC monitor, IMO.

Well, I suspect the books that Tom mentions are a bit too old to mention the method of moments (My Jordan & Balmain 2nd Edition doesn't, I know the 1st edition of Kraus doesn't & I lost my Jasik some years ago). The Method of Moments approach as it applies to electromagnetics has been around since the late '60s - I think Harrington's book, _Field Computation by Moment Methods_, published in 1968, was one of the first to deal extensively w/ this approach. A review of the Proceedings of the IEEE, IEEE Transactions on Antennas & Propagation, and IEEE Transactions on Electromagnetic Compatibility (just to name a few periodicals) from 1967 onward will reveal a fair amount of papers written on the application of the Method of Moments to a variety of problems.

It is not just "have in common". We need a format that is free and will not become obsolete. Unfortunately, the tool vendors like to lock you in. Not all of us use dos/windoze. There is also Mac and a variety of unix systems.

For netlists, Spice is the obvious choice, possibly with well documented extensions. Every good analog simulator either can use it directly or has conversion utilities available. (to the extent that the features overlap)

For schematics, postscript seems like a good choice on a quick glance, but there are problems. The plus side is that some systems have it built-in, and some printers use it directly. Postscript previewers are available for anything, sometimes free (Ghostscript). All good drawing programs can generate it, at least indirectly. The down sides are that may not be editable, it may not be possible to convert it back to something that it editable, and it is hard to extract a netlist from it. Some programs can edit a subset of Postscript. (Illustrator) But how do we convince the others to stick to the subset that can be edited?

How about demanding an annotated Spice netlist? It is easy to add coordinates to each element. How about 2 sets each -- one for schematic, one for layout. It is easy to make a tool to strip them out for Spice. It should be easy to patch the simulators to ignore the extra fields. The simulators could actually make use of the layout info for interconnect analysis. Since many schematic programs will output a Spice deck, they could be changed to preserve the locations. Maybe someone could make a simple viewer for it, and make it available on the net for free. How about an anno-spice to postscript converter? (master's project, perhaps?) Any takers?

Please don't make me buy any particular tool, especially one that doesn't run on my machine. Free ones off the net are no problem, as

long as they have source and can be compiled on my machine.

Thanks TGB,

Now let me ask a silly question. What part of "MOM" relates to
understanding how to operate, construct, or maintain an amateur radio
station?

If it can only be found in specialized engineering textbooks or
publications from the 70's, and if it is only one method of analysis
method dealing with EM fields, why the heck did someone stick it in an
amateur exam? Or is the object of the new Ham tests just to test
memorization instead of understanding?

The guy complaining may have gone a little overboard, but let's be
honest.....it is a obscure question to place in an amateur radio test.
Especially when fundamentals are often misunderstood and yet much more
important.

>understood is Drive power to the crystal.

Drive power used to be important way back when tubes were used and folks needed to squeeze the maximum number of watts out of the minimum number of tubes. In that case it was often a single-tube power oscillator connected to an antenna! When you're pushing a 6V6 oscillator to cherry-red plate condition, it's easy to get enough feedback through the crystal to damage it.

Nowadays, unless you are trying stunts like that, drive power maximums and crystal currents are something you should never have to worry about.

Date: 1995-09-24 00:00:00 UTC
From: pdrunen@aol.com
Message-ID: <4453d1$5p0@newsbf02.news.aol.com>
Source record: 110422

I picked up at a local hamfest what appears to be unused "WAX" type capacitors with long leads made by the American Capacitor Company. They appear to be in working condition, however, I don't know if this type has a selve life or not.

Anyway, if anyone has a need let me know, I Would like to get 0.25 cent each plus postage.

Chicago Condenser 312-227-7070
Condenser Products 800-382-6874
High Energy Corp. 800-732-5405

All of these should be capable of meeting your needs in quantities from 1 to many. There are many others listed in the "Capacitors, High Voltage" section of the Thomas Register. I have purchased capacitors uot to 5,000 joules energy storage from all of the above. As I recall High Energy Corp had the best prices for one offs, but the others rapidly dropped in price as a function of quantity. Be sure to give them sufficient information about your application. Peak discharge current, RMS current, and frequency of charge-discharge cycles are important parameters that can affect the design (and size and price) of a capacitor. If they don't ask for such information beware!

4404. Crystals in cordless phone

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-24 00:00:00 UTC
From: calhoun@gorge.net
Message-ID: <AC8A1B3D9668175ED1@205.162.195.2>
Source record: 110424

I have a cordless phone that has stopped working. It emitted harsh static and then nothing. I thought it was the battery and hooked a 9v battery to it. I heard static, but no dial tone. I popped it open and tested a few components (I am not big into electronics). I noticed that there were two boards inside. The first board had two of what I believe are crystals. They are pink and about 1/2 inch square approx. They are as follows:
QX-293
16.5567

QX-359
46.155

There is another crystal on the other board marked:
qx-237
4.192

I used an ohm meter to see if there was any resistance on these. Only the one marked 16.5567 had resistance. Also, on the first board there is written:
tx rx 4890

Can anyone tell me a little bit about what I am seeing? I figure at the very least I can salvage the 9v out of the unit and convert it for use with my handheld although the handheld wants 12v. Will that damage it if I use only 9v?
dave

: >>could you email jdubin@american.edu? Thanks!

: October 1990 Radio & Electronics Magazine had an article that described
: a circuit for doing this. A place called Harmonic Research in Paramus, NJ
: sells boards that implement the circuit in the article. I built one and
: it works fine. They also have boards to go from RGB to NTSC and other
: RGB stuff.

I built one for a friend and was impressed with the quality of the parts.
But I've heard the color processor chip has been obseleted by Motorola.
In addition, the output was only multisync EGA, as no scan rate conversion
was done. We hooked it up to a CGA monitor to test it, and the analog
outputs combined with the TTL inputs on the monitor made for some interesting
special effects.

Tom
read your msg on putting these older radios back in service on the ham bands. My son and I bought some Motorola Mitreks and are converting them. These were a matter of recrystaling and replacing one cap and rewinding a small coil. All this is done in the frequency elements and then retuning the radio. I have had good luck with the first one (just finished it).

I would like info on the conversion of a 450 Mhz MICOR.

Let's discuss

4408. Cable TV Converter Schematics for Spectrum Anal.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-24 00:00:00 UTC
From: Mark Hillier <Mark@HVWTech.com>
Message-ID: <44282q$s8h@stills.pubnix.net>
Source record: 110512

Hello,

I am still looking for a SCHEMATIC for a cable TV converter; any make, any model. This is to help a friend of mine with a project to 'repair' a spectrum analyzer he has.

Thanks to all those who responded to me previous post. Alot of useful info came to light. However, nobody seems to have an actual schematic!

Since these things are so cheap to produce, I expect that there were not alot of places that bothered fixing them; so, no schematics. But they have to *exist*.

Anyone ?

As usual, happy to pay for photocopying etc..

Thanks,

Mark, VE2HVW

Hi,

I've started to compile a "List of Stamp Application" (L.O.S.A for short). I think there are lots of *GREAT* ideas and problems solved with the BASIC Stamp and the main purpose of this list is to read what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

So if you have done something with the BASIC Stamp (small or big) that you are willing to tell others please use the form below and write a short description, nothing fancy is needed just a simple explanation. If you have source code to share thats even better but it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

When there are a bunch of contributions I'm going to post the L.O.S.A to this newsgroup and upload it to Parallax, Inc. FTP-site. I will update it approx. once a month.

Source record: 110518

Hi OM. You must be one of the LOWFERS that experiment in the 160 to 190 kHz range! Yes indeed Litzendraht wire is still available but horribly expensive. The only source I know of is: Kerrigan-Lewis Wire Products, 4421 West Rice Street, Chicago, Ill 60651. Telephone 312/772 7208

Getting information on the use of Litz wire is even more difficult. The best write up on this is in the LOWDOWN newsletter for April 1987 where the Hudson Wire Company 1962 Technical Inforamtion Guide is reproduced.

For the very basics, you must go back to Fred Terman, "Radio Engineering Handbook" First Edition 1943. Subsequent editions will NOT do. This issue is a collectors item nowdays! 73 and luck Cliff Buttschardt W6HDO

I have run up to the same problem. One solution is to go to your local electronic
parts store (not Radio Shack) and ask for a NTE-222. I believe Mouser has a line of these also. My findings are that this Mosfet is equal to or hotter than the 40673.

RF Parts still has some in stock, a little pricey at $6 a pop. They have an ad
in the back of about every third QST.

If you have an electronics house or TV repair shop nearby that can get the NTE
replacement line, the NTE222 is the suggested replacement. NTE221 and NTE454
are also dual-gate MOSFETs. All of these are about $3-4 each.

Newark has the Motorola MFE201 for $1.24 each, but have a $25 minimum.

Hello - thanks for reading this.

I am trying to repair an ancient Yaesu FT207R handheld.

It needs a replacement IF transformer. The original is a TOKO MMC 586N. I haven't been able to find this IFT in any of my TOKO catalogues, so I assume it has gone obsolete.

Can you help with either:

1. A source in the UK for the TOKO MMC 586N, or

2. An equivalent from TOKO's current range for this IFT, or

3. Data on the MMC 586N so I can choose a similar IFT from TOKO's current range.

Thanks if you can help, and thanks for taking the time to read this even if you can't help.

Does anyone know if Toko sells direct in small qty? Digi-key seems to be out of stock on the more popular parts and I was wondering if there are any other distributors that carry Toko? Does Toko accept Visa/MC orders of qty (1) like Mini Circuits?

Thanks,
- Cliff

4424. FCC Rules? Music and Repeaters, Roger Beep!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-25 00:00:00 UTC
From: raiar@inlink.com
Message-ID: <446tk2$o3b@news1.inlink.com>
Source record: 110433

FCC Rules? Music and Repeaters Roger Beep!

Beethoven's 5th - di di di dah

di dit di dah di dit dah dah dah di di di dah dit dah di dah dah
dah dah dah di di dah - A popular song!

Is Morse Code music, of course not, it's a form of communication. Morse Code is usually sent as a continuous wave and the receiver adds modulation to the carrier to obtain a pleasant and easy to read tone for the listener.

However, repeaters, some communications devices, etc. use a tone modulated carrier to achieve an audible Morse Code for ID purposes. A good example of this technique is your local FM repeater's automatic IDer.

The repeater control operator and others now have the ability to determine which frequency tone they will transmit as their ID and AR signal (courtesy tone). This ability to control the audible frequency has led to many sysops using tones that are both pleasant and sometimes musical. Which poses a rather interesting question concerning the FCCs Rules about music.

Before I ask my question or open it for discussion, I would like to add that the reason for posting in homebrew is two-fold. Most of the multi-toned modulation devices are homebrew projects or operator add-ons', secondly, this is one of the newsgroups I subscribe to and read regularly.

This is not a complaint about the practice of using multiple tone IDers, but only an opportunity to open for discussion a new topic to enlighten our knowledge and brighten our day.

Over the past year, I have noticed more and more repeaters moving to using multiple tones, some have carried this practice to using harmonic triad (definition below) notes. Recently, I have heard a total of nine (9) of these notes played in succession as an AR signal (courtesy tone) that was not a CW message or ID.

****
So now I have this question:
How many notes, harmonic triad or otherwise, can be played in succession before the FCC considers it music as defined in their rules?
****

Thus far I have spoken with three agents and received three separate answers which included.
1. Music is defined as the transmission of broadcast type music (records, tapes or live), singing and whistling, or the transmission of notes from a musical instrument.

2. The CW IDer can be modulated at any frequency the operator
desires in or out of audible range. Changing the tone frequency
is not a violation of our rules.
3. Any transmission of a signal that is musical in nature is a
violation of the rules.

That's government intelligence for you! Looks like they don't even know.

From a musical standpoint, a note is not considered music, until enough
notes are placed together to create a full-measure or bar. Dictionary
definitions are shown below.

The Merriam-Webster Dictionary
music \n 1: the science or art of combining tones into a composition
having structure and continuity; also: vocal or instrumental sounds
having rhythm, melody, or harmony 2: an agreeable sound
3: punishment for a misdeed

Webster's Encyclopedia of Dictionaries - New American Edition
Chapter/Section - Webster's Dictionary
music n. the art of combining sounds or sequences of notes into
harmonious patterns pleasing to the ear and satisfying to the
emotions; melody; musical composition or score.
Chapter/Section - Music Dictionary
music - Art and science of expression in sound
harmonic - referring to harmony; partial or overtone.
harmonic triad - three tone chord composed of a root tone, the
third and fifth above.

From the above definitions of the word "music", I feel we would all be in
trouble with Uncle Charlie!

Commentary Welcome

TTUL - 73+ de Gary - N0ZOI

Source record: 110435

I live in the country. Too bad, right? My favorite FM stereo
station is 100 miles away on 102.1 FM. The problem is an
FM station 5 miles from my house transmitting 50KW on 101.9
FM makes it impossible to recieve it(the 102.1 station).
When the 101.9 station is off the air (only during a power
outage) the 102.1 station 100 miles away comes in nicely.
Is ther some kind of filter I can install to suppress the 101.9
station. It does splatter onto 102.1 by the way. I know there
are filters out there but my problem may be unique because
of the closeness of the unwanted station and the long
distance of the wanted station. Please post if you have
a response. Thank you very much!!
P.S. I don't plan on moving to the city thank you...

: find a good used TV w/ a baseband video input rather than trying to kludge
: up a PC monitor, IMO.

Well, I'm just trying to use my monitor as a very nice display... after all, why bother spending another $200 on a similarly sized TV (15") when all I really need is my VCR and a NTSC-->RGB converter?

I looked at the article in Popoular Electronics mention earlier in the thread. It turns out that the device is about $99... too much to justify getting. Also, this is about 5 years old... there has to be something more current.

Thanks for the tips!
Jeff

Hi folks !

Am wondering if anyone has a good source of info/prices on (relatively) inexpensive RF relays ? I see a lot of "Guardian Elec." brand relays in amps, but have never seen a catalog that has them. I'm looking for SPDT and DPDT with ratings <= 110w @ 50 ohms at 440, and <=200 watts @ 50 ohms at 144. Something with a good loss/life/cost balance would be nice.

Thanks,
Jim Barber, N7CXI

james P. Meyer (jimbob@acpub.duke.edu) wrote:

: Drive power used to be important way back when tubes were used and
: folks needed to squeeze the maximum number of watts out of the minimum
: number of tubes. In that case it was often a single-tube power
: oscillator connected to an antenna! When you're pushing a 6V6
: oscillator to cherry-red plate condition, it's easy to get enough
: feedback through the crystal to damage it.

Drive power back then was important because they were trying not to
SMASH their crystals.

: Nowadays, unless you are trying stunts like that, drive power maximums
: and crystal currents are something you should never have to worry
: about.
: Jim "no sig" Meyer

Nowadays drive power is important because modern packages have
excellent thermal insulation and milliwatts can cause enough temp rise to
make a crystal oscillator drift further than the crystal's accuracy spec.

Modern expectations of frequency stability are now far higher than
back in the 1-tube days. (Modern crystals also have far lower
self-destruct power levels, too).

You SHOULD still worry about crystal dissipation, just for different
reasons, though..

Cheers

: "equivalents"; 3N204, MFE131, NTE221, NTE222, 3SK73, 3SK39, 3SK40, 3SK45,
: 3SK48, 3SK72 , TA7274, 3N200, 3N204, 3N211, 3N212, 3N213, TA7150, 40673 and
: (my own contribution); Philips BF981, BF982 (little flat pack critter).

Not all of these devices are "drop-in" replacements for the 40673.
Some definitely have different bias requirements, and others may have
too much gain for the original 40673 application.

The BF981 definitely requires different bias, and is much "hotter"
than the 40673. It may wake-up an old VHF front-end, but might
cause interesting problems if you try to use it at say 10.7MHz.

: are filters out there but my problem may be unique because
: of the closeness of the unwanted station and the long
: distance of the wanted station. Please post if you have

Well, you could build a rather expensive, hard-to-tune filter
that would kill much of the RF that is within the channel
assigned to the 101.9MHz station. Unfortunately, the nature of
FM modulation is that there are sidebands that extend "forever"
up and down from the carrier. The ones very far removed from the
carrier frequency are extremely low amplitude, but you are so
close to the station you don't stand much chance with a filter.
There is probably too much RF from the offending station that actually
falls within the channel of the desired station, and no filter will remove
that.

What offers a tiny possibility is an antenna with gain, and
perhaps more importantly with a null. If you can point a deep null
at the offending station and quite a bit of gain at the desired
station, and if you can put the antenna up high enough that the
desired station becomes truely line-of-sight, you may have a chance.
If you can manage a 20 or 30dB differentiation between the stations in this
way, I think you have a chance.

Only other thing I can think of is to get the 102.1 station to put in
a translator in your area that puts its signal on another frequency. But
since you are out of their primary service area, they aren't likely to be
sympathetic...

>FM makes it impossible to recieve it(the 102.1 station).
>... Is ther some kind of filter I can install to suppress the 101.9
>station.

There may be a solution, but it will not come from filtering. Filtering can solve interference for alternate channel interference (i.e., stations 400 kHz apart), but this requires an FM receiver with excellent selectivity (i.e., expensive). Filtering alone will not solve adjacent channel interference such as you have described.

What you need to do is increase the signal level of the desired station while simultaneously reducing the signal level of the undesired station. Depending upon the geometry of your situation, this may not be as implausible as it sounds.

First: So long as the undesired station location is not in-line with the desired station, you can reduce the strength of the undesired station by using an FM yagi antenna and nulling the closer station. (The common TV/FM log-periodic antennas will not provide anywhere near high enough side rejection. The antenna needs to be a Yagi.)

Second: Installing a high antenna will significantly increase the signal level of the desired station relative compared to the undesired station. (The local station will stay about the same amplitude, while the distant will increase amplitude.)

Third: The geometry of your situation must be considered when selecting antenna gain. If the local station is nearly broadside when your antenna is pointing to the distant station then you should use the highest gain yagi antenna you can find. If not, then you need to consider the antenna beamwidth when selecting an antenna.

Good luck,
Bill Sorsby, P.E. and ham operator N5BU

No, you still have to worry about it. If you simply throw
together a crystal oscillator using say a 2N5179 running from a
12 volt supply and use "typical" component values, it is very easy
to end up with 5 or 10 mW of crystal dissipation. If you turn this
oscillator on and off with PTT, you may notice an annoying drift
on the beginning of each transmission. The oscillator will in
general have poorer stability than one running at "sane" drive
levels (well below 1 mW).

Don't throw away the whole concept because you've had some bad luck.
Do it right and it'll work just fine.

>If you really want to switch, I'd suggest you get a relay rated for use at
>70cm. But these are usually kind of expensive, and then you have to have
>power to drive the coil.

They don't have to be expensive... if you know where to look. Try
the Aromat relays distributed by Master Distributers in Oakland and
Santa Monica, California. Particularly the RF, RK and RG series.
These were designed as a cheap automatic A/B switch for TV's and
VCR's. They are spec'ed at over 1 GHz with insertion loss as low as
3 dB at 900 MHz. And isolation like you wouldn't believe! You'll
find them configured for SPST, SPDT, DPDT etc. They are designed for
PC mount so there IS a little work involved, but you end up with the
connectors of your choice when you're done.

I was turned on to these by John Quinn who designed RF Concepts latest
dual-band power amp. I liked them so much I designed them into an amp
my old company built and sold for Motorola. 50W was no problem for
these little relays. (As long as you didn't hot-switch them too many
times.)

>Sorry things aren't simpler at UHF, but that's the way it is.

I agree with that statement, but what makes it fun is doing what the
average guy can't. :-) Mike - KD6PKJ

A distributor for Guardian Electronics is Newark Electronics,
one of the big electronic distributors.

However, I suspect that the relays you saw weren't designed
for RF use. To cut costs, manufacturers will often use ordinary
relays and design the circuit to minimize the effect of the
impedance bumps.

Typically, amateurs aren't going to go through all that trouble
to characterize inexpensive relays. Instead, they will spend hours
going to flea markets or rallies to find surplus relays designed for
RF applications. Typically, these relays will go for about $35,
though they often set back the original purchaser $500. A problem
with surplus relays is that they typically are designed for 24
volts--surplus 12 volt RF relays are relatively rare, though they
can be found. Sometimes they can be rewound--the snag is taking
them apart without breaking something.

4450. How to Interface aging Kaypros for CW keyers

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-26 00:00:00 UTC
From: rdkeys@csemail.cropsci.ncsu.edu
Message-ID: <4496ad$93i@taco.cc.ncsu.edu>
Source record: 110459

For a programming project, as a last gasp practical use to make some aging kaypros in the bilges of the hamshack sing again, I would like to make the things toggle rs-232 lines (data lines or control lines) to actuate external reed relays which will key a radio transmitter at a data rate (morse code specificially, although rtty or other modes would be nice too).

I have a program that runs fine on my Xerox 820-II that toggles the ports and keys remarkably fast and cleanly (much better than my PC's do when running similar software). Unfortunately, when I change the ports to make it run on the kaypros, it does nothing. There seems to be something very minor different between the control of the serial ports on the Xerox 820-II vs the kaypros.

On the xerox the ports for the keyboard are 1Eh and 1Fh for data and control registers. On the kaypros I tried ports 4 and 6 for the serial output but port 5 (i think or maybe 7) to get keyboard input did nothing.

Can anyone tell me the correct data and status register ports for the Kaypro II and the Kaypro 4-84? Also, can anyone confirm that the standard serial modem port is 04h-data/06h-status?

Also, does anyone know of any software other than the tiny bit on oak in the sigm 141 file and the oak/cpm/hamradio directory, that is related to the use of serial or parallel ports to toggle external relays, controls, or other devices, etc? I would love to gather up any and all amateur radio related CP/M softare before it becomes vaporware.....(:+{{.....

I am particularly interested in any programs that run CW on CP/M machines or log using such machines.

Does anyone know if it is possible to toggle all bits/lines on the serial or parallel ports in unison (so that one could, in theory, fan out more ttl loads than just a single line could)? Some reed relays may overload the ttl fanout load power that the single lines could control. If it would be possible to toggle all lines in unison, as if one were sending a break down the line, then that could be sufficiently powerful to drive heftier relays without the need for additional interfacing dongles or boxes (my current interface fits inside an RS-232 plug shell). Some of my boatanchor transmitters key via rather hefty 28 volt relays so hefty reed relays are required.

Thanks again, and may your fine little CP/M boxes ply the digital bitstream waters for many fine moons to come! Nothing wrong with a rack-mounted Kaypro as a CW keyboard amidst the boatanchor hamshack!

(What the heck, aging kaypros at 3 or 5 dollars a pop in the electronic fleamarkets should make great little dedicated controller boxes, in lieu

of multi-kilobuck pentium laptops.....(:+}}.....)

Hi Robert,

If you want gain the spacing is different than null depth. So do you want
a deep, dide clean null or just maximum signal level with less rejection
of unwanted directions?

73 Tom

>>..... NEW JERSEY ANTIQUE RADIO CLUB
>>..... RADIO SWAPMEET

>>..........Saturday, October 7, 1995

>>.......Hightstown Country Club Ballroom

The New Jersey Antique Radio Club will present its all-outdoors Fall swapmeet at Hightstown, 7 AM to 1 PM, with seller setup beginning at 6:30 AM. Vendors will be offering a spectrum of collectible old-time radios - table-model, console, transistor, Bakelite, communications - with related literature and parts. Food and beverages available. Ample on-site parking for $2. Everyone is welcome!

Directions: The location is off NJ Route 33, reached from Exit 8 of the New Jersey Turnpike. From the Turnpike exit, go east on Rte. 33 about 200 yards past Mom's Peppermill restaurant. Continue . mile to the first jughandle and loop west. At the first traffic light, bear right onto Monmouth St. Look for the white building, the "Hightstown Country Club Ballroom," about 300 yards on the left.

For out-of-area visitors, accommodations are available at the Ramada Inn directly across Monmouth St. [(609) 448-7000]. On Rte 33 nearby are the Day's Inn [(800-DAYS-INN, or (609) 448-3200] and the Town House Motel [800-922-0622 from out-of-state, or (609) 448-2400 within New Jersey].

Seller rates are $15 per table ($3 discount to NJARC members). To reserve a table, please send a check payable to NJARC to: Onalee Fisher , 344 Harrison Ave., Manville, NJ 08835 by Oct. 3. Contact: Onalee Fisher at (908) 725-7476.

Formed in mid-1992, NJARC now has a membership above 120. The club meets at Grace Lutheran Church on Corner of Old Route 33, Park Ave., and Rt 537, Main Street, in Freehold, New Jersey on the second Friday of each month at 7:30 PM. Visitors are welcome. For details, see any recent issue of Antique Radio Classified or the AWA Old Timer's Bulletin.

Wilderness Radio's NorCal 40A (40 meter QRP CW Transceiver kit) is now available with a very good Spanish translation of the manual. A second product, the KC1 universal subminature keyer/frequency counter kit (2.5" x 0.8"), will also soon have a Spanish translation available. Contact Bob Dyer, KD6VIO, at 415-494-3806. Or write to Wilderness Radio, P.O. Box 734, Los Altos, CA 94023-0734, U.S.A.

>coax also?

>Thanks,
>Kory
>KE6VWO

Well, yes and no to all these questions. Actually, if you run coax to
the switch and keep the leads short, the little mini-switches that
mount in a 1/4" dia hole aren't all that bad. I've done switching
with them at 500 MHz. and don't expect half a dB loss.

One trick that I have used to advantage is to use a shielded box for
my A/B switch using BNC connectors in and out. Then I use a #22 wire
mounted five wire diameters above the chassis (this is what is called
air-dielectric microstrip) to make a 50 ohm transmission line out of
the wire and the chassis ground. Only when the wire has to go up to
the switch and the center post of the connector do I go above the
5-diameter separation.

Or one can use an electronic circuit to temporarily boost your 12 volts to 24 to make the relay pull in. Usually 12 volts will be enough to keep the relay pulled. It will use less current as a bonus. I 'designed' and used such a circuit long ago. My design wasn't all that complicated, 2 transistors, some diodes and some passive components, but an improvement in that it didn't have the recovery time that the original circuit had. Using a lower holding voltage probably has disadvantages, too. Perhaps somebody can enlighten us on that.

Somebody asked about such a circuit half a year or so ago. I hope I've still got the ASCII artwork somewhere.

: How many notes, harmonic triad or otherwise, can be played in succession
: before the FCC considers it music as defined in their rules?
: **********

I continue to wonder why the FCC should care anyway. As with many of
their other rules I guess.

Anyhow, you bringing up Beethoven's 5th got me thinking, what if you
were to use sort of an FSK/Morse combination, such that the carrier frequency
shifts a little bit for the various notes, and the music thus can be
heard by beating with your BFO? That would certainly be stretching
the definition of music a bit... you're not modulating the carrier with
music, only with information which can be used to create music. Just
so happens that every receiver designed for CW could hear it, that's all...
And, if your "song" had rhythmic patterns that corresponded to Morse
characters, and you got caught, you could always just say that you really
did intend to transmit all that gibberish, and dosh-garnit, the bloody
oscillator in the transmitter happened to be feeling flakey right about
then and....

I bet some hacker somewhere messed around with RTTY music, picking the
right data sequences to achieve a similar effect... heck, if it can be done
with a dot matrix printer why not?

Cliff,
Try Penstock. There is undoubtedly a phone number for them in the
LA area. They are the only other distributor for TOKO that I know of.
They don't normally sell in very small quantities, but you might try
them for samples. I've had good fortune with them in this regard when
trying to get a working prototype together in a hurry.

>volts--surplus 12 volt RF relays are relatively rare, though they
>can be found. Sometimes they can be rewound--the snag is taking
>them apart without breaking something.

Often you can just swap the 28 volt coil for a 12 volt coil from a more
conventional (read cheaper) relay. And also surprisingly frequently
a 28 volt relay *will* work at 12 volts without tinkering. The relay
manufacturer often designs in quite a bit of margin, and if the spring
has lost a bit of its "sproing" the relay will work at the lower voltage.
Sometimes you need to hit the relay with a spike to make it pull in, but
it will then hold at 12 volts. Obviously this won't always work, but may
be an alternative for using an available relay in a one-off project.

The reduced holding pressure may cause contact burning, so you need
to watch out for that.

4470. Re: Two-tone FM transmitter deviation test? help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-28 00:00:00 UTC
From: geertj@ripe.net
Message-ID: <DFM3uo.50B@inter.NL.net>
Source record: 110379

In <449k8v$83g@mari.onr.com> ct@onr.com (Charlie Thompson) writes:
>I understand that there is a way to set FM transmitter deviation
>using two audio tones.
>Anybody out there familiar with this technique?

I think you are mistaking FM and SSB.
Two tones are used to test an SSB transmitter. The reason is that
with one one, the output of the transmitter is (should be) just
a single carrier. With two tones, you can test linearity and such

To set the deviation of FM, you can use another trick, which is based
on FM theory. The theory says, that for certain values of the modulation
index, the carrier completely disappears. So, of you have an unmodulated
signal and add modulation, you add sidebands:

```
| |
| |
| => | | |
--------------- ---------------
```

For small values of the modulation index, only the first sidebands
are visible. If you add more deviation, the carrier gets smaller
and smaller, disappears, and reappears again:

```
|
| | |
| | | => | |
--------------- ---------------
```

The first time this happens is at m=2.4. Now, how does this help you?

Assume that you need a deviation of 3 KHz. Get a sine generator and set
it to 3000/2.4 = 1250 Hz. Connect to transmitter and set modulation to 0.

Take a SSB receiver and tune it to the carrier of the FM transmitter.
Tune to get a tone that is easily recognized, say, 400 Hz.
Now slowly increase the modulation. You will hear all kinds of rubbish
but only pay attention to the 400 Hz tone. At a certain amplitude, the
tone will be nulled out. Measure the amplitude you used to get this;
that is the amplitude needed for 3 KHz modulation.

Hope this helps,

Geert Jan PE1HZG

I've been away from this newsgroup for a while and just read things for the first time in weeks.

I would like to suggest that interested readers that want a copy of an excellent circuit simulator get a copy of APLAC. APLAC is a very versatile circuit and system level simulator. A "DEMO" version is available at the following location:

http://picea.hut.fi/aplac/general.html

APLAC is a windows program that is "spice like" and much like touchstone. The demo version is very, very little disabled. The only restrictions that are stated are that it limits file sizes to 256 K bytes and that the interface drivers that allow the import of s parameters from your network analyzer are disabled.

It does not have a schematic input but it is compatible with PSPice and touchstone files. There is a schematic program called NASSE that does draw a schematic and create a file but it is limited to 10 components. APLAC has files for about any component you might want including stripline and I beleive even rat race mixers. It does not do artwork however (I beleive).

I can't remember how big the files are but I beleive they are around 2 meg or so before unzipping. There is extensive documentation available that is also downloadable. The manual is several hundred pages long and is over 10 meg long. It requires a postxcript printer to printout. A friend of mine has printed out around 100 pages so far using "Ghostscript" to his inkjet printer. The manual includes full graphics including schematics of examples response charts and smith charts.

I have only looked through some of the samples that are included in the demo program. Note that the word "DEMO" is what Helsinki University and and the Nokia Coeporare Research Center call it. Most of us would call it a full featured program.

What I have seen of it makes me very entheustic. It appears to be a professional program that I can afford ($0.00), costing only download time. A friend of mine copied his via Prodigy so anyone with web capabilities should have no problem.

I'm anxious to have others run it through it's paces and either confirm my limited experience or to shoot holes through my story.

What do you guys think?

4475. Hand-mike REPAIR-Tip

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-28 00:00:00 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.812307090@eagle.csl.uiuc.edu>
Source record: 110384

I was successful in renovating damaged Dynamic Handmike (probably 600 ohm-Z) which had been ruined by dropping it on the cement floor. The small internal P-C board with transistor was mounted to the voice-coil terminals, resulting in severing the tiny voice-coil wires in such a way that it was almost impossible to repair. Radio-Shack sells an "Electret" unit for $1.99 which has wide frequency resonse, but requires supply voltage of between +2 volts and +10 volts. Substituting this unit alone, although it worked, did not supply enough output (This particular mike was a Motorola series 500 from a SSB C-B transceiver..cat# 550). In order to utilize the original transistor which had amplified the original voice-coil, I substituted a 100 ohm resistor for the bad voice-coil and removed a 1.0 uf by-pass capacitor. But now a supply voltage is needed for the Electret unit (ideally +4.5 v thru 1K load-resistor to the Electret). The only voltage in microphone unit was via the collector load resistance to the original transistor amplifier....which is a class-A amplifier with "average" +6v at its collector. Since my Electret unit only consumed about 1/3 ma, I simply filtered out the audio-swings from the collector through a 4.7K to a 220 ufd, which provided about +4.5 DC. Then from here, the recom-mended 1K to the Electret....then a 10 ufd coupler from the Electret output to the base of the original transistor. This yielded just the amount of audio that I needed....a little more than 100% modulation on AM with loud talk into the microphone. There was no gain-control, so this is also the correct level for SSB operation. Viewing on oscilloscope showed no observable distortion. These guide-lines could probably be implemented in a wide variety of hand-mikes used in Amateur-Radio and C-B equipment, that have been damaged by water or dropping.

I once heard a Toko salesman say that they consider 100,000 pieces to
be a small quantity, and won't provide free samples to customers
working in those volumes.

Do yourself a favor, and work within the constraints of Digi-Key.

From: Zack Lau <zlau@arrl.org>
Message-ID: <44er37$s8e@mgate.arrl.org>
Source record: 110386

I noticed that HP has come out with a new SOT-363 package, which is significantly smaller than SO-8 packages.

I have been able to point to point wire SO-14/SO-8 ICs without a magnifying glass, so these seem to be OK.

Anyone have comments on how easy/hard they found it to work with these new parts in amateur homebrew projects?

Looks like the MGA-87563/MGA-86563 might be useful for making miniature microwave transceivers for taking on hiking trips.

I happen to have some extra IC's (assuming I can still find them).
Anyone want to buy some?

>In addition, the output was only multisync EGA, as no scan rate conversion

No, the output is NTSC analog (15.734 kHz. horiz sweep). EGA is a
digital interface, there is no way it would ever work for TV, even
with scan rate conversion.

Advice from idustrial experience:

I design some circuits that run 5+ years on a set of batterys.
(O.K. they are lithium cells)

If my assemblers or technitions leave ANY flux on these boards, they
WILL malfunction, due to high impedances needed to save batterys.

I use "Hydro-flux" or "Organic" core solder exclusively.

This can be cleaned with water, but I use some dishwashing soap and a
toothbrush, followed by plain tap water rinse.

Boards are then dried with dried, filtered compressed air.

The problem with using alchohol is that nobody ever uses enough. They
just dissolve the flux, smear it around, the alchohol flashes off,and
leaves a thin flux residue which is invisable but can give 1 MOhm or
less between traces easily. I have also seen FR4 boards "stained"
where flux residue is carried into the fibreglass!

Water is cheap, (even in desert where I live) and no problem using
enough of it.

Another advantage of using water in industrial setting is that the
EPA doesn't care how much you use, or what you do with it!

At home, I use same process on my projects. If working on something
built with "rosin" flux, I scrub with alchohol, and rinse with soapy ,
then fresh water before alchohol dries.

Other hams seem horrified that I put circuit in kitchen sink. Never
had any problems with this, and ABQ water is fairly hard. Give a
final rinse with DI water if you are worry wart, or have super bad
hard water problem.

Remove as much water "mechanically" (shake, blow or blot) as
possible, ions are deposited by evaporation process.

Buy solder at "real" store, or mail order (Newark, Allied, etc.) RS
has only the rosin core stuff which is near impossible to clean up.

BTW, on the "5 year boards" I can raise battery current 500% by
breathing (like when cleaning glasses) on them! Part of the reason we
pot them after test. Try this with SK III board, will give you new
respect for just how little current CMOS uses!

I used BF980's to add two extra IF stages to my Yaesu FT-757 to
wake up its *HF* front end. In stock condition, it's a real
dog on 10 meters. Now I can hear the increase in background
noise that occurs when the band is open.

Anyway, they worked great at the 8.XXX MHz. IF. I've never had
oscillation problems with them.

I can't stand watching this any more!

HERE's THE BLOODY QUESTIONS, RIGHT FROM THE ARRL INFOSERVER:

A9B09 (B)
What type of computer program is commonly used for modeling antennas?
A. Graphical analysis
B. Method of Moments
C. Mutual impedance analysis
D. Calculus differentiation with respect to physical properties

A9B10 (A)
What is the principle of a "Method of Moments" analysis?
A. A wire is modeled as a series of segments, each having a distinct
value of current
B. A wire is modeled as a single sine-wave current generator
C. A wire is modeled as a series of points, each having a distinct
location in space
D. A wire is modeled as a series of segments, each having a distinct
value of voltage across it

You'll notice it says "TYPE of computer program".

Sheesh.

>are pink and about 1/2 inch square approx. They are as follows:
>QX-293
>16.5567
>
>QX-359
>46.155

Yikes, 9 volts. Most cordless take around 3 to 4 volts on the handset to
operate. Check the voltage on the nicad battery pack after a charge.
The 46.155 sounds like a recieve crystal. If you add .455Mhz (a common
If in most cordless you come out on 46.61 Mhz which is a cordless frequency.
The 16.5567 is the transmit crystal and you times them by 3 to get the
handset transmitter frequency.

>
>There is another crystal on the other board marked:
>qx-237
>4.192

Possibly a crystal used in the generation of tones for the keypad. It
does not sound familiar. >

>I used an ohm meter to see if there was any resistance on these. Only the
>one marked 16.5567 had resistance. Also, on the first board there is
>written:
>tx rx 4890
>
>Can anyone tell me a little bit about what I am seeing? I figure at the
>very least I can salvage the 9v out of the unit and convert it for use with
>my handheld although the handheld wants 12v. Will that damage it if I use
>only 9v?
>dave
>
>Try using a portable general coverage reciever to see if the crystals are
operating properly by dialing up their frequency and holding the antenna
close to the handset and listen for a carrier. If you hear one shut the
handset down and if the carrier goes away you know that what you were hearing
was the crystal.
I have found that if the handset was not dropped and the batteries are ok

then it may be as simple as retuning the pilot tone most phones generate.

Be sure and check the base unit for the obvious things such as power loss
(bad adapter) or disconnection from the phone line.
Good luck. >

4487. HW16 Power Transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-09-29 00:00:00 UTC
From: a313@Lehigh.EDU
Message-ID: <44gnv9$3ctc@ns5-1.CC.Lehigh.EDU>
Source record: 110396

I have a Heathkit HW16 cw transceiver with a bad power transformer. The rig in cosemetically fine and worked well until I pluged in the external VFO. Apparently the additional load was too much to hadle and the circuit breaker opened after a few minutes. One of the windings has a very low resistance so all I get is the filament and negative bias supply voltages.

If anybody has a transformer for the rig or an old almost worthless HW16, I would be interested in a deal. Someday I would like to finish restoring this neat rig without expending an arm and leg or giving up the rights to my first born :-)

Hi Bob,
Your suggestion is good, but unless you want to go on for a very long time,
it would be difficult to cover the many topics that various folks have in mind.
Maybe it would be better to solicit questions, and then answer them from
your experienced point of view. Or, you can pick any item you want, that was
a "learning experience for you", and just post it. Maybe this is what you
had in mind, anyway...
Also, you might correct the spelling of "homebrew".

My Rx/Tx an ICOM H16T has been tuned by vendor and
my manual DOES NOT explain how to proceed with frequency tunning.
Each time I need some new frequencies, I have to send back my Rx/Tx
to the vendor and to wait one or two weeks for get it back to me.

PS: I don't use this Rx/Tx for myself, but for a charitable
association which provides all legal permits needed for frequency
use, and which also often changes, adds or removes some frequencies.

Please answer by mail to supermag@dialup.francenet.fr ,
(and don't expect too quick answer)
Thanks.

4497. HR2600 Mods?

Newsgroup: rec.radio.amateur.homebrew

From: DICENSODJ%DFL@pcmail.usafa.af.mil
Message-ID: <44hmcu$cfc@usafa2.usafa.af.mil>
Source record: 110406

Anybody got a mod for the HR2600 that'll let me reduce power below the accepted QRP 5 watt level?

I wrote Uniden, but got a rather impolite nasty-gram that implied serious repercussions if I were to modify my radio in any way...

Same punishment as tearing that little tag of your matterss, I guess.

Thanks for any suggestions!

- Dave WB1CDG / 7J6CCH

I have done some dead bug construction with SSOP packages (20mil lead pitch) but it was done under a microscope with very fine solder and small iron tip.

In many cases, I go right up to the device leads with .082 or the smaller .041 rigid coax for the ins and outs on MMICs and mixers etc. I have tried these techniques up as high as 6GHz with good results.

I have seen some reasonably priced stereo microscopes at the ham flea markets lately. Seems like a good thing to have in the home shop today. I sometimes wonder how much longer we will be able to buy DIP components and leaded Rs and Cs.

Have you tried using epoxy to glue the ferite slug back together?
You may want to look through the Digi-Key catalog if worse comes to
worse (1-800-344-4539). They have a good selection of tunable
inductors. Remember, *never* use a screwdriver on a tuning slug.
Always use proper alignment tools.

By the way, that is a nice radio you have. I had one years ago. I wish
I'd never sold it.

good luck,

>P.S. I don't plan on moving to the city thank you...

You have a number of problems here. The local station will be very strong. The distant station is very weak. Your receiver may lack sufficient selectivity to reject strong adjacent channel signal and is being desensitized (because the AGC circuit is reacting to the adjacent signal instead of the desired one).

Assuming that the unwanted station is not producing unwanted signal on the desired frequency, (because if that is the case nothing can help you), and because the two frequencies are 800 KHz apart, you MAY be able to produce a usable signal.

First, use as directional an antenna as possible to increase the wanted signal while decreasing the unwanted signal. Obviously having the unwanted signal in another direction from the desired one will help. If you have enough room, for example, the old ARRL Antenna Books used to describe a 144-MHz rhombic with an estimated gain of 27 db and a horizontal beamwidth of 8.5 degrees which should scale up to 101 MHz fairly easily. (You'll need a space about 100 feet by 40 feet, though).

Secondly, there are a number of trap filters you can use to try to reduce the amount of 101.9 Mhz signal entering your receiver. The ARRL Radio Frequency Interference Book shows the bandpass characteristics, for example, of the Winegard FT-760 tunable VHF-FM trap, designed for use in 75 ohm coaxial transmission lines - designed to notch out one or two FM broadcast stations. The notch is about 25 db deep.

If you can receive the desired station on your FM car radio, which generally has more sensitivity AND more selectivity than your typical home stereo, then there is probably hope you can engineer a solution.

>text for patch antennas. Neither Jasik nor Hamsher (my two antenna
>bibles) make any reference to a "patch" antenna.

This was an interesting article.

a)This book was in my work library, the last I looked. They sometimes lend
via interlibrary loan, but probably NOT to individuals themselves.
My library is at Lincoln Laboratory, Mass. Institute of Technology.
Your library could conceivably request it from us. Dave Pozar is at Univ. of
Massachusetts at Amherst, so their library would also likely have it. I think
Dave went to Ohio State, I believe, and that library would also likely have
it. Other likely libraries are Syracuse Univ., VPI, Univ. of Houston and
Arizona State? I'm basing these comments on which universities have active
research programs in patch antennas.

b)Another reference would be the IEEE's "Transactions on Antennas and
Propagation." Look in the cumulative indices under Dave Pozar, Keith Carver,
S. Long or P. Katehi. Patch antennas are also known as "microstrip" antennas,
so don't forget to look there.

: antenna >???

I have a 20-m X-beam on the roof. It's built according to the dimensions given in the manual (ARRL), though I had to trim the tails more than I expected (about 10 inches) to get a low SWR (about 1.2).

It was easy enough to build, and it's light: I have it on a short mast that's bolted to the end of a gable, and I rotate it with a Radio Shack TV-antenna rotator.

It's definitely an improvement over a dipole. It seems to have a few dB gain and somewhere between 10 and 15 dB front-to back ratio. It's got a couple of deep nulls on each side, which I can use to advantage.

It hasn't been through any really heavy weather yet -- no winds over about 35 mph and no snow.

So far, I'm satisfied.

>Thanks if you can help

I had a similar problem with a old Yaesu mobile transceiver some years
ago. Although the factory was prepared to supply replacements, the
cost was horrendous.
I scratched around in the junkbox and discovered that the slugs from
an old Panasonic tv chassis fitted and worked perfectly.
If you still have the pieces, they can be glued very successfully
using superglue. Glueing has little effect on performance.
To prevent future cracks, coat outside of slug with a bit of wax.

4511. Need circuit diagram for a 1 or 2 channel rf transmitter and receiver

Hello,
Call me a sucker, but I tried to use an LM380 as the PA
for an audio filter project. If I ever need a pink noise generator
I've got just the thing in my junk box now :-)
Could somebody suggest a low noise (i.e. very low hiss)
alternative that I can use with both headphones and speaker? Something
I can get from DigiKey or Mouser would be ideal. I only need a half watt
for speaker use, not the full power the LM380 is capable of. I'd like to
use a 9 volt supply for this but could go up to 12 or down to 5 or 6.

>

Last spring, I bought an old Standard 2 channel crystal controlled mobile radio that was originally set up for 460mhz. I got the manual, too. I was going to use it for 9600 baud TCP/IP. Someone had "converted" it to 446, by simply retuning it down. The radio was basically deaf. In order to "make it hear", I retuned the helical front end by removing the cans, and rewinding the coils - adding about 3/8 turn to each in the process. Standard included a table of front end filter coils in the manual for each of the bands this could be tuned on, from 400 to 470mhz (excluding 430-450). I interpolated to get the required size for 440.

I now have to go over the PA, and make sure it's clean. Output is down from spec, and tuneup was very touchy, so I have a feeling it's going to need some work. Now that I have a spectrum analyzer, I feel much more comfortable about tackling this.

This radio should be an ideal radio to dedicate to 9600. It's crystal controlled, and uses electronic switiching, so turnaround time will be very fast. Power output is rated at 12-25watts, if I remember correctly. It was fairly cheap - $50 with the manual. But I probably could have done even better. Conversion involves some work, though and the proper instruments.

If I ever find the time to finish this project, I'll write it up, I promise...

Most of the big vendors like Motorola, National etc. offer Spice models
on disk for many of their products. Call the sales offices listed
in the data books and find out who your local rep. is. They can order
the models for you. It helps to have a legitimate business need
for it so make one up if you need to.

Hi all

I'm looking for descriptions of passive antenna splitters, to use 1 antenna and several (at least 2) receivers. It has to work from 1.8 to 7 Mhz.

In fact, it's supposed to work with a beverage receiving antenna.

Have u ever seen that in ur readings ???

Thanks in advance and best 73s from Paris

Larry - F6FVY - lhaas@pratique.fr

I have used the LM380 without too much trouble in the past, but
you may try the LM833 dual audio op amp with both op amps
driving the load with about 10 Ohm isolation resistors.

Jim

I have not found noise to be a problem with the LM380. (Stability is another issue.) If you can tame the PS bypassing requirements, and sensitivity to stray coupling, and keep it from oscillating (took me 4 tries!) then the '380 is reasonably clean. It's distortion is not quite up to CD quality, but it sounds as good as anything else on say "Dolbyed" cassets. A lot of lower end car stereos used this chip (with 'house' part numbers) 10-15 years ago, and none were excessivly "Hissy".

Hiss in general comes in at low level/high impedance points of circuit, not at PA level. If you are running PA at high enough gain to hear it's hiss, then you are asking for all kinds of trouble in other areas.

I hope you are using an "audio-grade" amp at lower power level locations in your circuit.(ie active filters) A lot of the good audio amps (5534, TL071 etc) won't work well with only 9V between the rails. Haven't had reason to use new single supply amps yet, but unless you have low noise spec, assume it's a hisser. If you are using a switching technique to generate a negitive rail, it is a prime culpret for your noise source. Connect filter output to your stereo's Aux input to rule this out. If it's still hissy, you needn't work on PA.

In my experience, hiss often comes in via the power supply lines. Are you "baising up" the audio path from the PS because of single 9V rail? Even very good linear voltage regulators have some "hiss" on them. (esp the popular 78XX and 79XX series regulators) There is just no substitute for passive (RC or LC not just C!) decoupling/filtering on the PS lines. and do not derive bias from any unfiltered source. If you use tantilum caps for bypassing, it will probably work. If you use aluminum electrolytics with 1 uF ceramics in paralell, it might work, or you might have to experiment with values. I have found this to be true with many high power amps: LM-12, 2005, 380 etc. That high current output just wants to couple into everything.

If you must bias '380 inputs from PS, make sure that both inverting and non-inverting inputs "see" same impedance to ground, and same impedance to PS at all audio frequencys, not just DC. this allows PS noise to cancel. I used this this trick on a digitally controlled,

clickless attenuator circuit once, and went from "hissy " to dead quiet. I could see no PS noise on 'scope, judt output.
My mistake had been in putting cap to ground on reference input..I replaced cap with circuit simulating output impedance of driving audio stage, and ALL noise vanished.

LM380 is adiquate for all communication applications....But not up to high end audio like you want from a stereo system.. It actually has enough "headroom" to sound pretty nice in comm applications.
Also, consider what impedance levels exist at you amplifier inputs. anything over 1K and you will start picking up BC, computer noise etc.

Ultra sonic oscillation can sound like hiss sometimes, so look at output with a 'scope.

hope something here helps, and good luck!

Source record: 110336

Do NOT try and run the LM 380 with less than 12 volt power supplies!
They do turn into noise generators even with many micofarad of supply
bypassing. Use an LM 386 instead, even if a nine volt battery is used.
Some LM 380's are OK at lower voltages but why try and find the units
that will work at the lower voltage? 73 de Cliff W6HDO

I like the Philips TDA7052. It gives 1.2 W into 8R at 6V, and needs
virtually no external components. The gain is fixed at 40 dB, it needs
no heatsink, and produces no power on/off clicks. 8-pin DIL package, and
quite cheap!

It's theremin. I built one from a kit about 25 years ago, I think it was
advertised or featured in Popular Electronics. If you can get an index
for PE you might find it. It was nearly impossible to keep tuned due to
temperature changes but it was a neat toy. I'm sure there are better
designs now. It's just an oscillator circuit with capacitive adjustment
(via the hand or body).

Yes, I have had the same experience. I have since replaced
it with a LM383 (also known as a TDA2002, CA2002, or ULN3701Z).

It comes in a five pin TO220 package, cost about $2.50.

It is certainly not noiseless either, but is much better than that
lousy LM380.

I did experience some instability though, which I finally cured
by feeding the 12v via a 7808 voltage regulator (or was it a 78L09?).
The current limit feature of the regulator stopped the instability
(motorboating: self explanitory if you ever hear it). Even at reduced
voltage, there was plenty of volume for bother speaker and headphone work.

Later, I noticed the same type of current limit circuit applied to a
LM380 in one of the ARRL QRP books.

4535. 300 V Low Cost RF Power MOSFETs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-03 00:00:00 UTC
From: ilkka.kontola@nmp.nokia.com
Message-ID: <ilkka.kontola.72.000D6B6A@nmp.nokia.com>
Source record: 110344

RF Design Aug 1995 cover story "Low Cost 1000 Watt,
300 Volt RF Power Amplifier for 13.56" describes a
class C 1 kW amplifier using four MOSFETS.

The ARF444/ARF445 MOSFETs are manufactured by
Adcanced Power Technology. What is unusual with these
MOSFETs is the plastic TO-247 package. Also the 300 V
operating voltage simplifies the power supply a lot.

If these MOSFETs were as inexpensive as the article hints
and if one could get decent IMD in linear amplifier use
they would revolutionize HF amplifier homebrewing.

Personally being more declined to VHF/UHF weak
signal work (but somewhat active on HF) I would be
delighted if one could with 100 W drive (IC-736)
get, say, 500 Watts output on 50 MHz using these MOSFETs.

Does anyone have any experience or at least more data
on these MOSFETs?

The lack of harmonics is easily rectified with a "fuzz" circuit employing diodes. The real disadvantage to these devices is the lack of multiple, simultaneous notes (chords). Nowadays, you can create the same effect as a theremin with any good synthesizer, although the method of control is different.

I remember a complete construction article for a theremin in Popular Electronics, back in the mid-60's. The device was pictured on the cover and I think it used triangular plates for each surface. One plate controlled the volume, the other the pitch. These devices work on the same principle as metal detectors.

I remember reading that article, and if my memory serves me correctly, due to the high gate capacitance and other characteristics, you would be hard pressed to use these devices much past the medium frequency range. I think these devices were developed for switching power supplies whose frequencies of operation are in the hundreds of kiloHertz. I doubt if you could get anywhere close to VHF operation out of them.

How about a standard op-amp with a power stage added? A single
complementary pair - emitter follower should do it. Put it inside
the feedback loop. With a pair bootstrap capacitors, you won't
lose voltage swing. Use whatever op-amp meets the input and
gain-bandwidth requirements.

Bob:

Interesting application !
As it happens, I still have a mint Kaypro II in the closet. I can
verify that you have the ports right; perhaps you aren't programming
the UART (I don't remember what chip they use) correctly.
If I remember correctly, you have to set the control register to
a specific bitmask to enable the handshaking lines. It's been
8-10 years or so since I fooled much with 'em, but I'll take a look.
Do you know if they used the Z80 SIO ? I still have the docs for
all the "native" Z80 peripherals on the "retired" shelf.

As to CP/M software, There are still a couple of CP/M UG's around
the country. It probably wouldn't be a bad idea to sniff around
for some archives; I'll look into it when I have a little time.

BTW: I have a NorthGate Advantage (with 5mb hard drive) that needs
a home ! Anyone ?? For free ??

I think they're named after a fellow named Leon Theremin, their inventor.
Joseph Schillinger, the musical theorist, (tried to marry music and math)
wrote some music for theremin. They never caught on musically because
they're short on harmonics. Just another curiosity like the heckelphon,
or the musette. If you build one, don't practice when your neighbors

4547. Solder + silver conductivity

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-04 00:00:00 UTC
From: whiting@cadence.com
Message-ID: <DFx3Gx.41n@Cadence.COM>
Source record: 110356

Hi,

I've been build some microwave stuff and find that solder
containing silver (eg 60/38/2% tin/lead/silver) is
recommended for this.

In other descriptions, normal tin/lead solder is said to be
lossy and should not be left around in cavities, etc.

The question (for you materials science types) is this:
Does a 2% silver content in the solder do anything to
sognificantly reduce the (resistive/skin effect) loss of
solder, such that I don't need to worry (so much) about
removing it from cavities, or would the silver content
have to be much higher to do this.

(It may be that this solder is recommended to avoid silver
leaching problems with smd components, rather than for
conductivity reasons?)

73,

Neil

Sounds like you're getting lots of good advice. One more point I didn't hear mentioned was the noise generation of typical 3-terminal regulators with band-gap references. These guys are very noisy unless you bypass the output with a good 10 uF or larger capacitor. If you're using a single supply, you probably have, somewhere, a voltage divider to get a voltage of about half the supply voltage. Typically, you apply this to the input of the first stage. This is an excellent place for noise from the supply (or anywhere else) to get in. Use large resistors for the divider (assuming you've designed things so very little current is required from this reference) and use a big capacitor at the divider's output.

(By the way, zeners aren't necessarily any better. They can be extremely noisy under some circumstances, too.)

Golly gee... Maybe if you tried the Theremin Home Page you would find more than you ever wanted to know about Mr. Theremin and his weird musical instrument. Don't have the web address so whip up Yahoo and see what you find. And let's not minimize the effect of the theremin. It has been used extensively in the recording of popular music since its introduction. Usually a few of the top 40 songs are still using it today. The Theremin also was the foundation for the evolution of the development of electronic instruments.

Oh, GROSS. Why would you want to destroy the unique and wonderful
sould of a perfectly good instrument by this kind of uncool garbage.

>Nowadays, you can create the same effect as
>a theremin with any good synthesizer, although the method of control is
>different.
>

I SERIOUSLY beg to differ -- to get the effect of a theramin, you need a
REAL theramin. You just can't get the pitch/volune shift effects or
tonality with a keyboard, mod wheels and CV pedals no matter how good a
player you are. There is simply no keyboard synth which can properly,
and in any but the most meager and unmusical way, duplicate the sound
that can be extracted from the real thing in a performance situation. As
far as being monophonic, well, that's just the way it is -- its a solo
instrument. You can't play cords on a trombone either ... And I
certainly wouldn't want to listen to one played through a fuzz box.
Yecccch.

For the gentleman who asked the question, there are very modern theramins
which are still available commercially. Best source would be to call
around to music shops which cater to the professional musician. They
should be able to put you in the right direction. Not being a theramin
player by skill or trade, it would take a while, but I might be able to
find a current reference or two. I have seen some theramin references
Keyboard or Electronic Musician magazines sometime in the past couple of
years or so.

Rather than posting here to rec.radio.stuff, you should be able to find
an appropriately musical newsgroup on USENET, where you could get some
definitive answers on the subject. Some of the synth vendors are on line
(Ensoniq, etc.) and they might be willing to point you to a source if you
send to their E-mail. Also, in the MIDI related forums on Compuserve
there should be some answers, if you have access to that service -- a lot
of expertise there (circuit info, too) and many vendors on-line as well.

You might also check your local library for electronic musical instrument
references -- books in the period 1930-50s or so (I don't really know the
right time periods).

Regards

Grant/NQ5T

Well, well, there are _two_ Teds in Houston. The Theremin Home Page is at

http://www.vuse.vanderbilt.edu/~jbbarile/theremin.html

There is another reference in the folk music area.

There are kits available for <90 dollars with a case at under 80.

C'mon Grant, everyone knows that anything less than 50% THD isn't *real*
music. The effect is kinda nostalgic, actually. Reminds me of the old
Akai Cross-Field recorders with the bias head out of alignment. We used
to record guitar licks this way because the effect wasn't as harsh as the
diode method.

>I SERIOUSLY beg to differ -- to get the effect of a theramin, you need a
>REAL theramin.

That must be why synthesized guitars, pianos and violins don't sound like
the real thing. They just fool 99.9% of the people 99.9% of the time.

>You can't play cords on a trombone either ... And I certainly wouldn't
>want to listen to one played through a fuzz box. Yecccch.

Yeah, they said the same thing about guitars until Jimi Hendrix came along.
Actually, didn't "real" musicians berate the industry for electrifying the
instrument in the first place?

This reminds me of a client I had once, who replaced his 50's vintage hi-fi
with stereo equipment I recommended. We ended up having to disconnect the
tweeters in the Klipsch Cornwalls so the music would be more "mellow", the
way he was used to hearing it.

It's all in the ear of the beholder, Grant.

Just pulled up '380 data sheet (been a while since I used one, 10 yr maybe)

Paint my face red!

I was confusing this with '383..Sorry guess my memory is going.
Apply my earlier comments to '383 chip, not '380.

Now then, looking at the '380 data sheet:

Make sure you have a CERAMIC (not electrolytic) .47-2.2 uF cap from pin 1 to your low level signal ground.
(filter input reference, not gnd pins of '380 chip, which should be tie point for PS, and speaker return)

The fixed gain of 50 and Zin of 150 K are both awfully high for a PA stage...just begging for trouble.

I'd try 10Kohms to signal ground from pin 6. run a 47k in series with a cap (>=1uF,SWAG value, + to pin 8 if polarized) feedback from pin 8 to pin 6 for a gain of ~6. connect input via 10K from pin 2 to preceeding amp output.

Cap is required in feedback due to self biasing (Vcc/2) scheme. 10K input R to pin 2 is optional, may help or hurt depending on layout.

lower gain PA will let you use more of the dynamic range in your low level circuits, (~20 dBgreater S/N ratio) and perhaps reduce your hissing.

Check to make sure this didn't disrupt output biasing scheme (doesn't look like it aughta) if so, add a 10uF cap in series with pin 6 R to ground.

These fixes may be easier than scrapping '380 circuit.

Again, sorry to fuel confusion, 73.

Hi Scott,

This ain't gonna be easy. I remember seeing construction articles for
these a long time ago. You're gonna have to find a library with old
copies or micro film of the construction oriented electronics magazines
of the '60's.

The best first step would be the guide to periodical liturature (ask the
Librarian if you're not familiar with it) you just pick the year, look
up "theramin" and it will tell you every mag where this subject was
addressed.

Good Luck es 73 de KE4QOK

I have been asked to research how different amateur radio clubs make innovative use of technology to communicate to, and with their members. I have volunteered to research this issue for the Montgomery Amateur Radio Club in Maryland. My goal is to present a report to the membership on how others are using packet, the internet, BBS services, voice mail, and even programmed repeater announcements to keep the flow of information in front of the members. I feel strongly that the time has come to consider the club newsletter as only one vehicle for the dissemination of information. Your comments are appreciated. If you are a member of a club, please share with me what your club does, or what you wish they did do.

When all responses are compiled I will make the total file available for anyone who wishes to see it.

Thank You.

Bingo! Silver solder (2%) isn't markedly more conductive
than ordinary soft solder, but the silver content does reduce
leaching problems. It also offers a bit better mechanical
bond. In contrast, high silver content *hard* solder gives
a much stronger bond, and is also much more conductive, but
the melting point is too high for most electronic applications,
but not for things like cavity finger stock or finger stock
used for tube contacts. Then *hard* silver solder is just
the ticket (you need a torch).

4560. Odd behavior of 4CX1000A

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-05 00:00:00 UTC
From: wrt@eskimo.com
Message-ID: <DFzMps.HLD@eskimo.com>
Source record: 110275

I have just finished a homebrew amp using a 4CX1000A and it works fine, with one small exception: The plate current drifts a bit depending on the temperature of the tube. For example, I have the idling plate current set at 250 ma as recommended by the Eimac data sheet, but when I drive it to full output (1500 watts) and then remove the drive, the plate current drops back to about 220 ma and then climbs back up to 250, taking about five seconds or so. I can also see this after I have it tuned up -- I apply drive (continuous carrier) and the plate current rises to the normal 800 ma or so, then drifts down about 20-30 ma and stabilizes there. This drift is NOT in any of the supply voltages. It's definitely in the tube itself. The supplies are:
Plate: 3000 volts loaded, 3400 volts unloaded
Screen: 355 volts (shunt regulated)
Control grid: -62 volts (for 250 ma idle)
Filament: 6.1 volts

Is this normal behavior or do I have a tube starting to go bad? The tube is an old one (1960's era), but the fellow I got it from said he won it at a hamfest and it's been mostly sitting on a shelf all this time.

Anyone have a known good one for sale? Wouldn't hurt to have a spare, I suppose.

From: jpll@vectorbd.com
Message-ID: <DFzwv3.DJ2@vectorbd.com>
Source record: 110280

Here's some better related info

Free space path loss is

Lfs(db) = 37 + 20*log(d) + 20*log(F)

where d is distance in miles, and F is frequency in MHz.

For 30 miles and 444 MHz, the free space path loss is 119.49 db.

>Also, What is the calculation for figuring how much gain in the antenna I'll
>need and beamwidth etc.....

Well you need to know the required signal strength at the receiver to
achieve a 20 db quieting. That's typically in the 0.5 microvolt range.
Applying P=E^2/R, and assuming a system input impedance of 50 ohms,
we have a required signal level at the receiver of -143 dbW. With a
one watt transmitter, we're starting with 0 dbW, and must subtract
path loss from that giving a signal of -119.49 dbW at the receiver
with *no antenna gain*. That's a fade margin of 23.51 db with isotropic
antennas at each end. So if you *really* have a free space path between
the sites, simple 1/4-wave omni antennas will suffice. To determine
the signal level at the receiver, you apply the following formula,

Er = sqrt((10*10^(Txp + (Txant-TFeed) - PL + (Rxant-RFeed)))/50)

Where Er is in volts, Txp is transmit power in dbW, Txant is transmit
antenna gain in db, TFeed is feedline loss in db, PL is path loss in
db, Rxant is receive antenna gain in db, and RFeed is feedline loss
in db.

Now you probably *don't* really have line of sight between the sites.
30 miles is near the radio horizon for an antenna 1000 feet HAAT. So
you'll have additional loss. You have to figure loss from objects in
the path, such as trees, houses etc. And if you really have terrain
blockage, say by a ridgeline, then you'll be communicating by forward
scatter or tropo. An equation that will give path loss in the forward
scatter case is as follows,

Lsc = 126 + 30*log(F) + 20*log(d) + 10*A - 0.2*N

Where F is frequency in MHz, d is distance in miles, A is the scatter
angle in degrees, and N is the radio refractive index of air over the
scattering path. N is expressed as

N = 77.6*P/T + 3.73*10^5*e/T^2

Where P is pressure in millibars, T is temperature in Kelvins, and
e is water-vapor pressure in millibars. Typical sea level value for
N is 324.

Working your problem with a scatter angle of 1 degree, we get a
path loss of 180.16 db. So you'll need combined antenna gains at
the transmitter and receiver of 37 db to make the trip on 1 watt.
Increasing transmit power to 45 watts (16.5 db) would help considerably,
allowing antennas with 10 db over isotropic on each end.

Tropo ducting will allow path loss to fall somewhere between the line
of sight case and the pure forward scatter case.

Happy Days,

Hope to have a short list of electronics parts,Kits & Amateur
Radio shops in Perth.Will be going to Perth,Australia Soon.Hope
to visit some of the Shops.

Thanks

>and if one could get decent IMD in linear amplifier use
>they would revolutionize HF amplifier homebrewing.

First of all, these are NOT linear devices and IMD's would stink. You have to understand the market at the 13.56 MHz ISM (Industrial, Scientific, Medical) band to know WHY low cost/watt is critical. I wont go into that here. The transistors are driving a load-line that is critically matched for very high efficiency and good power out, but only at 13.56 MHz. If you wander off of that freq. with that circuit the efficiency will go down, the device dissipation will go up, and the transistors will blow. The plastic package can only dissipate so much. You can design a different circuit at another frequency and possibly get it to work, but you will only get good results over a narrow bandwidth. Let me add, getting it to work will be no small feat either. It's a catch-22: you have to drive it hard to design and tune the correct load-line for it for the best efficiency/power out, but you CAN'T drive it hard until it IS correct or it will over-dissipate and blow.

There's a good reason why the article was published. It was not an easy task to accomplish. Mr. Lee Max who assisted in this design is one of the best in the industry. I visited with him a couple of days ago when he dropped by our facility. If we all has his talent and patience, many amplifier houses would go out of business.

For home-brew, I recommend sticking with the more rugged, tried and proven, mobile 13.6V transistors. If you want to play with MOSFET's, the MRF150 is really easy to work with if you've got 40-50V handy and can give you pretty good linearity also.

>P.S. I don't plan on moving to the city thank you...

Unless you take a hell of a lot of trouble, I would think you will find it difficult to construct a filter with the required Q, to sepparate two stations 0.2MHz apart at 100MHz. You would need a Q of about 1000 to attenuate the strong one by only 3dB, so to get 20dB or so, you would need a Q of several thousand. A well constructed cavity could do it, but a simple band-pass LC will not. Crystal filters can be made to do this sort of thing, but you would probably have to spend $500 to get one made for your frequency, but its cheaper than moving house!

A directional antenna would be a simpler bet. If the two stations are located 90deg apart in direction, you are laughing, as a beam has a null at 90 degrees. Aim the antenna at the week one and the stronger one will disapear. If they are close to 90 degrees, you might be able to null the strong one out, by pointing it at right angles to the boom, but *not* aiming the beam at the weak one. This will give slightly lower signal to the weak one than would be the case if beamed straight at it, but much higher signa to interference ratio.

If they are sepparated by a small angle, you will have to get a high gain antenna, and rely on aiming at the weak one, and hoping the attenuation of the side of the beam is enough.

In theory you can make an antenna and place the nulls where you want them, but its not trivual to work out the maths, nor to build the antenna.

One possibility, if you dont mind a bit of experimentation is to try to actively cancell the strong signal. Take a beam and aim this at the weak one. Take a small whip, which will pick up mostly the strong one. Add the signal from the two antennas together, after introducting both a variable phase control and amplitude control. If you can make the two signals form the local station of the same amplitude and opposite phase, you can cancell it. I've done this to cancell unwanted signals in

circuits before, when filtering was not an option.

One possibility might be to build a receiver with a good quaility multi-pole crystal filter in the IF stages. At the end of the day, unless the strong station is actually transmitting a poor signal, it is a receiver fault. Ceramic filters used in most receivers dont have the selectivity of crystal ones. You could probably get a decent receiver in module form, then feed its audio back to HiFi.

List Of Stamp Applications (L.O.S.A for short)
==============================================

If you have done something with the BASIC Stamp (big or small)
that you are willing to tell others please use the form below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in
the L.O.S.A form on the Web-page...

http://www.algonet.se/~cj/losa.html

When there are a bunch of contributions I'm going to post the L.O.S.A
to this list, upload it to Parallax, Inc. FTP-site and send it to the
following Usenet groups. I will update it approx. once a month.

4573. Re: R2 Single Signal Single Conversion Receiver - Experiences?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-06 00:00:00 UTC
From: Jim Strohm <jstrohm@blazer>
Message-ID: <453f7l$9ej@unisql.unisql.com>
Source record: 110282

I have an R2 / T2 pair "in the works" (well, actually, buried in the junkbox until after the next time I move).

1) Order the commercially made circuit boards!!
2) Follow the parts recommendations in the articles, especially for the capacitors. For the phasing filters, a lot of same-value, different-part-number caps WILL NOT FIT, either in the PCB holes or in the spaces between the components.
3) If you can custom-match the phasing L and C parts, you'll get a better performing rig. You need an LCR bridge or similar, and probably 10 friends who are also building R2 / T2 projects to get rid of all the extra parts you'll need to buy to get good matching components.
4) I had no problem whatsoever getting parts, but at the time I was living in the Dallas/Ft. Worth area, and had excellent access to a number of well-stocked surplus houses. Digi-Key and Mouser provided excellent service for the mail-order parts they stocked. For the Mini-Circuits mixers, I was able to find some at a swap fest. However, Mini-Circuits accepts small orders and Visa/MC. For convenience you may want to batch your order with those of your 10 friends...and ask for the RF Designer's Guide, and order some of their other fun RF goodies like MMICs.
5) Read the instructions carefully, look at the diagrams until you've memorized them, and be advised that there was at least one correction printed in QST a few months after the R2 plans were published.
6) Although it's mentioned in the plans, it bears repeating -- socket the ICs or you will never be able to get them out of the PCB if you have a bad one or a failure later.

Hope this helps

Jim

4576. Re: Solder + silver conductivity

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-06 00:00:00 UTC
From: w7el@teleport.com
Message-ID: <454afm$era@maureen.teleport.com>
Source record: 110285

```
; whiting@cadence.com (Neil Whiting) writes:
; Hi,
;
; I've been build some microwave stuff and find that solder
; containing silver (eg 60/38/2% tin/lead/silver) is
; recommended for this.
;
; In other descriptions, normal tin/lead solder is said to be
; lossy and should not be left around in cavities, etc.
;
; The question (for you materials science types) is this:
; Does a 2% silver content in the solder do anything to
; sognificantly reduce the (resistive/skin effect) loss of
; solder, such that I don't need to worry (so much) about
; removing it from cavities, or would the silver content
; have to be much higher to do this.
;
; (It may be that this solder is recommended to avoid silver
; leaching problems with smd components, rather than for
; conductivity reasons?)
```

I really don't know about cavities, although I'd be surprised if the small silver content has much of an effect on conductivity.

The main use for 2%-3% silver-bearing solder is as you said, to avoid leaching the metallization from SMD components. I've done some experiments and have found that leaching isn't a problem with solder-terminated parts, but is with palladium-silver and gold-terminated parts, and the silver content does help in the latter cases.

From: snorris@netcom.com
Message-ID: <snorrisDG1r4A.4t5@netcom.com>
Source record: 110287

I'm looking for a filter synthesis program. Preferrably for windows and has the following capabilities.

LPF, HPF, BPF
Butterworh, Chebyshev, Elliptic, Bessel, Transitional Gaussian, etc, (as many types as possible)
component tolerances for yield analysis would be nice but not neccessary.
graphical schematics would be nice too for use in design reports
Good for RF frequencies
active compnents would be nice as well, but not neccessary.
Fairly reasonable cost or even shareware.

That's about it. I'm doing my own research right now, but if anyone has some suggestions, I would love to hear them.

Sean

I don't have any experience with that, but
the thought occurs to me that perhaps using
sheets of laminating plastic would work.

4581. J pole antenna using COAX instead of twinlead for its stub

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-07 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDG292y.MEI@netcom.com>
Source record: 110290

A J POLE ANTENNA USING COAX FOR THE STUB

Instead of 300 ohm twinlead.

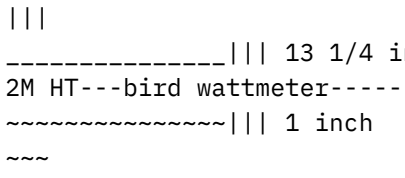
Decided to try using a piece of RG58 coax in place of the usual
300 ohm TV twinlead. They're both transmission lines. So, a
quarter wave length of eighter should work (factor in velocity
factor in measuring out a quarter wave length, twinlead is 0.88
and RG58 poly is 0.66). And the coax is unbalanced, so no
theoritical need for a choke balun (ferrite beads or many turn
coil). The coax shield is at RF ground potential, the RF is
on the center conductor, and the open end of the quarter wave
stub center conductor connects to the end of the half wave
dipole. The tap is formed by "T" connecting the stub coax
to the coax feedline from the radio.

Take some RG58, short shield to center conductor.
Measure 13 1/4 inches from the short, remove the outside jacket
and shield at this point and beyond. Leave an inch or 2 of
center conductor sticking out.

Measure 1 inch from the short, and prepare to do a "T" connection
here. Create a hole in the outer shield about 1/3 inch long
and peel it about half way round the coax. Then take a razor blade
and remove enough insulation from the center conductor to bare a
small spot. Enough to do a tack solder connection, which connects
to the center conductor of the feedline coax. And shield to
shield. Take care to get a good connection without shorts.
Take your time here. One probably could just use a BNC T connector
here, and make a short shorted cable for one side, and a longer
cable to feed the dipole on the other. Just keep the overall
lengths right.

Now connect a length of wire to the center conductor sticking out
the open end of the stub, enough so the length of the wire and
the amount of center conductor protruding beyond the end of the
coax shield totals 37 1/2 inches. This is the dipole part.

ASCII attempted diagram: |
|
|
|
| 37 1/2 inches
|
|
|



13 1/4 inches (includes below
1 inch)
1 inch

Used a 2 meter HT and a Bird wattmeter to measure forward and reflected power, indirectly SWR. My forward power was ten times reflected power, not bad. At one point, I had a bad T connection (bad solder joint) that caused the forward power to almost equal reflected power. Fixed that, and now it works like the twinlead Jpoles. Ran my hand along the feedline coax, and the stub, no effect on reflected power. Did get reflected power if I get near the dipole part, as expected.

And I could hit repeaters pretty well, considering I was in the basement.

Naw, this tube uses an oxide-coated cathode. But it also has a grid
rated for 1 ma; no wattage rating at all. The behavior being
described is pretty much what I was used to seeing when I ran my 30S-1
up into grid current. Grid leak would shove the bias up and the time
constant of the bias circuit was quite long. That doesn't eliminate
the possibility that something's happening at the cathode--especially
when you say the output power is 1.5 KW. The extra current might be
changing the emissivity of the cathode. I did not see this effect
when I switched over to 4CX1500B's (unless I went into grid current)
so the grid might be involved too.

If you have a power supply available, or the parts to build one then it would be a fun project. You will need something in the neighborhood of (roughly) 700 volts at 200 mA. Depending on frequency you should get about 40 or 50 watts output. It might be cheaper to build an amplifier from solid state components if you can't scrape together a power supply.

Fred's correct about this. I've seen the same effect in 8877's also. It's a common mox cath problem when the tube is near its ratings.

No it's sure not 50 ohms, it's usually very high Z. The antenna it matches is a short unloaded voltage probe, so the input of the rx has to be very high Z to not load it.

SF>-anywhere. Would anyone know where I can get more information on them
SF>-(I'm not even sure I'm spelling it correctly)? Or better yet, would
SF>-anyone have any plans floating around for building a theramin?

Hi Scott,

This ain't gonna be easy. I remember seeing construction articles for
these a long time ago. You're gonna have to find a library with old
copies or micro film of the construction oriented electronics magazines
of the '60's.

The best first step would be the guide to periodical liturature (ask the
Librarian if you're not familiar with it) you just pick the year, look
up "theramin" and it will tell you every mag where this subject was
addressed.

Good Luck es 73 de KE4QOK

>suppose.

>73, Bill W7LZP
>wrt@eskimo.com

YOUR FILIMENT VOLTAGE COULD BE DROPING DUE TO EXCESSIVE INPUT VOLTAGE
DROP. IF THE FILIMENT VOLTAGE IS AT OR BELOW THE KNEE OF FULL
EMMISSION AND THEN DROPS AS LITTLE AS .1 VOLT THE PLATE CURRENT WILL
TAKE A SUBSTANTIAL DROP. CHECK THE FILIMENT VOLTAGE WITHOUT TX KEYED
AND WITH TX KEYED. VOLTAGE SHOULD NOT DROP BELOW RATINGS FOR THIS
TUBE. ALSO OPERATING A TUBE WITH INSUFFICIENT FILIMENT VOLTAGE IS
ACTUALLY HARDER ON SAID TUBE THAN OVER VOLTAGE (TO A POINT ANYWAY).

Subject: R2 Single Signal Single Conversion Receiver - Experiences?

Hi,

Have any of you built an R2 direct conversion receiver at all? This was
published in 1992 in QST: basically it was a "phasing" SSB receiver.

I'd be interested in exchanging experiences with other builders ...
especially on sourcing of components, local oscillators tried (DDS
anyone?) and DSP'ing the backend of the receiver.

>>..... NEW JERSEY ANTIQUE RADIO CLUB
>>..... RADIO SWAPMEET

>>.....Saturday, October 7, 1995

>>.....Hightstown Country Club Ballroom

The New Jersey Antique Radio Club will present its all-outdoors
Fall swapmeet at Hightstown, 7 AM to 1 PM, with seller setup be-
ginning at 6:30 AM. Vendors will be offering a spectrum of col-
lectible old-time radios - table-model, console, transistor,
Bakelite, communications - with related literature and parts.
Food and beverages available. Ample on-site parking for $2.

Everyone is welcome!

Directions: The location is off NJ Route 33, reached from Exit 8
of the New Jersey Turnpike. From the Turnpike exit, go east on Rte.
33 about 200 yards past Mom's Peppermill restaurant. Continue .
mile to the first jughandle and loop west. At the first traffic
light, bear right onto Monmouth St. Look for the white building,
the "Hightstown Country Club Ballroom," about 300 yards on the
left.

For out-of-area visitors, accommodations are available at the
Ramada Inn directly across Monmouth St. [(609) 448-7000]. On Rte
33 nearby are the Day's Inn [(800-DAYS-INN, or (609) 448-3200]
and the Town House Motel [800-922-0622 from out-of-state, or
(609) 448-2400 within New Jersey].

Seller rates are $15 per table ($3 discount to NJARC members).
To reserve a table, please send a check payable to NJARC to:
Onalee Fisher , 344 Harrison Ave., Manville, NJ 08835 by Oct. 3.
Contact: Onalee Fisher at (908) 725-7476.

Formed in mid-1992, NJARC now has a membership above 120. The
club meets at Grace Lutheran Church on Corner of Old Route 33, Park Ave.,
and Rt 537, Main Street, in Freehold, New Jersey on the second Friday
of each month at 7:30 PM. Visitors are welcome. For details, see any
recent issue of Antique Radio Classified or the AWA Old Timer's Bulletin.

First I want to say I am sorry that this has nothing
to do with the topic of this group. You may see this
message in other newsgroups, the reason is I am subscribed
to those too so please don't flame me. I have been posting
and reading to this group for a while. I just wanted to
let you people out know there is a way to get Cable TV for
FREE. I recieve this letter in the mail from a friend
that had told me it works. I gave this to one of my friends
and he had free cable in his house within 20 mins. I have not
tried this method yet but may soon try if my cable goes up in
price. If anyone would like a copy send the following to the
address below.

Address Envelope to:

FreeStuff
9393 N. 90th St.
Suite 102-289
Scottsdale, AZ 85258

Enclose in the envelope:

Send...

$1.00 U.S MONEY *** NO COINS *** NO CHECKS ***
inside a sheet of carbon paper or construction paper,
and send a *self-addressed*,*stamped* envelope to the
address above.

Thanxs,
Just think if you pay 30$ + a month. 1$ will save
you 359 + dollars a year.

4593. PLL/VCO homebrew designs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-07 00:00:00 UTC
From: hduff@humnet.humberc.on.ca
Message-ID: <8007-326281702@humnet.humberc.on.ca>
Source record: 110302

I'm in the process of designing a PLL/VCO to eliminate the need for
crystals on a bunch of lowband GE mobile rigs that my club aquired for
use on 6 meters.
I plan on using the serial MC145157 along with a PIC or 87C750 single
chip micro and a VCO made up of discrete parts.

I'd like to hear from some experienced designers of LPF/VCO circuits
for your suggestions/comments.

Thanks !

The cable used on car antennas is 125 ohm's or 93 ohm's dependend what
manufacturer used.

4595. Re: Filter synthesis prog.??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-08 00:00:00 UTC
From: Mike.Czuhajewski@bbs.abs.net
Message-ID: <1995Oct07.204833.21272@abs.net>
Source record: 110304

There is a good freeware filter synthesis program available at lehigh.edu via ftp. It's by Bob Lombardi, titled Filter Design System or something similar, and the filename is something like FDS124. It does low pass, high pass, bandpass, Chebyshev, Butterworth, elliptic, and is a good one. (He won honorable mention several years ago when he submitted an earlier version to RF Design magazine for their annual design contest.) There is no analysis available in the program, but for that I use GPLA, General Purpose Ladder Analysys, by Wes Hayward, W7ZOI. It's part of the software suite that comes with the ARRL reprint of Wes' Intro to Radio Frequency Design. (True Story: at work, one of the other technicians went to a local ham store and bought the Hayward book specifically to get the software. For him, the book was a bonus!)

To get the filter synthesis program, do anonymous ftp to ftp.lehigh.edu, and dig down the directory tree to

pub/listserv/qrp-l/tools [that's QRP-L, not QRP-1, but use lowercase when ftp'ing]

It's been a while since I uploaded a copy of Bobs program there, but I think the filename I used was FDS124 or something like that. (Ignore the short .txt file there; it doesn't say much, and is a very, very brief quote from the "on-disk" documentation.) I think it's a PKZIP'ed file (it's been a while since I uploaded a copy there).

If you use the output to disk function, which in the current version writes files in the Touchstone format, there are a couple warts; I mentioned them to the author. One gives an error which stops Touchstone from doing a sweep, so you know you have a problem. The other will work but give erroneous results, but only involves filters with different input and output impedances.

This is a very good program, well worth taking a look at.

4600. VHF Communications Magazine

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-08 00:00:00 UTC
From: Michael J Wooding <vhf-comm@g6iqm.demon.co.uk>
Message-ID: <69808943wnr@g6iqm.demon.co.uk>
Source record: 110309

Hi There,

To all subscribers issue 3/1995 of VHF Communications magazine will be shipped Monday Oct. 9th. We apologise for the slight delay, but as they say in the best circles, this was due to circumstances beyond our control - in fact our printing house had a major machine failure.

To anyone who is not a subscriber to the magazine, it is a publication for the Radio Amateur Worldwide, especially covering VHF, UHF and Microwaves. 95% of the contents are construction projects with a full backup with PCB's and/or kits. The worldwide subscription rate is UKP15.00 by cheque or UKP15.75 by credit card or bank transfer.

To whet your appetite the contents of the latest issue include:

A Frequency Counter with Harmonic Mixing
200mW GaAsFET Amplifier for 24 GHz
Part-6 of a DIY Receiver for GPS and GLONASS Satellites
Linear Signal Rectification

For further information please send me an email.

Regards ... Mike

The spelling for the device is theremin. That may help your searches.

Over 20 years ago, I dabbled with theremins. Most of them were based on the idea that a human hand placed near an antenna can change the capacitance of the device, which in turn changed the frequency of the sound.

Most of the flying-saucer sounds from science fiction movies of the 1950's were made with theremins.

What I have done is to use plain paper in the printer. I use a deskjet 540
and cover one side with clear packing tape or coat it with clear spray
paint after gluing it to the panel with contact cement or mounting spray.

good luck

Get hold of a product called TEC-200 film. It is used to transfer pcb
images onto copper clad board but it will work very well for your
need.
Place the film in the printer, print the designs onto the film, place
the film on your panel and apply heat and pressure (a regular clothes
iron works fine). After a few seconds,and after the panel has cooled,
the film is removed and the image stays behind.
Contact Meadowlake Corp at P O Box 1555 ONECO FL 34264.

>manufacturer used.

Yeah, but Tom's right, it is best considered a low capacitance shielded
cable, and not treated as a matched transmission line, because that's
not the way it's used. The input impedance of a Standard Broadcast
receiver using one of these voltage probe antennas is very high.

You can terminate your converter design in any convienent (moderate)
impedance and just *bridge* the AM radio input across that termination.
It will offer practically no loading at all to the circuit. That'll cost
you some voltage gain, of course, but that's not generally a problem at
these frequencies. It'll be easier to boost the voltage gain of the
post-mixer amplifier than to attempt a match to the AM receiver's
front end.

You can attempt a match, but it will be megohms, not 93 ohms, that
you'll wind up with as the match value. That can make for a really
squirrelly unstable converter, and is best avoided. If your converter
is for LF or low to mid HF, atmospheric noise will still set the SNR
of the system.

>supply; could it double as a p.s. for an HTX-202? Any ideas?
>I don't know what the amperage is though, not listed.

Sure you do, if it's rated at 13 volts at 10.4 watts, then the
formula P=IE can be manipulated to give I=P/E or 10.4/13=0.8 amps.

The real problems you'll face are with regulation and filtering.
In it's original form, the unit had a secondary battery in the
cellphone to act as the regulator and filter. If I remember the
HTX-202 external power circuit correctly, it is diode steered.
So the HTX-202 battery won't serve well as a filter and regulator.

I'd hang an auto courtesy lamp across it as a load and look at
the output with a scope before trusting my HT to it.

Source record: 110223

I've received a couple of emails in addition top the replies posted here.

There seems to be quite a lot of "extra" information available! I'm glad I asked!

I designed and made my own PCB last week - I added the "other" sideband circuit on-board and put right-angled BNCs on the inputs. I changed the biasing of the audio amp and reduced the quiescent current to 20mA (I heard from others who have done this too). I made the board "double sided", the top is a ground plane...I have always found that this method of construction works best.

It fired up first time and it seems to have pretty decent opposite sideband surpression. I am still playing around with VFOs. I just saw a nice DDS design in October's 73 Amateur Radio Today. I might make a version of this as an experiment.

By the way, Digikey's prices for the inductors for the R1/2 & T2 designs are not the best. I get mine from the UK, a place called Cirkit, who'll do credit card orders and air mail them over. They arrive in about 3 days and it costs about $8 for the shipping (not much more than continental USA!). Anyway, they charge 62p per 10RB inductor, that's $1 approx.....Digikey's price is around $3.50 I think! This place, Cirkit, has lots of other interesting RF things too - they are the main UK outlet for Toko. It's worth getting a catalogue shipped to you. Phone number is 011-44-1992-444-111 (Sales) or 011-44-1992-464-457 (Switchboard).

The impedence is rather high, several K ohms. Think of the typical AM
car antenna as a capacitive probe. You can not have much "loading" or
you will drop the rf voltage to nothing. Try terminating the radio
with around 50ohms at the converter output. Years ago I built a sw
converter and it was prone to feedback. A 50 (or 68 or 72 or 75) ohm
resistor cured the feedback. Remember that you can almost alway "bridge"
a hi z load across a low z source(except when actually transferring
real power). The only non antena exception would be with a transformer
output audio amp. If you leave the output open(or nearly so) you can fry
the output devices(either tube or solid state).
If the auto radio is an AM/FM there is most likely a terminating network
inside the radio. Back before I had a good home radio, I went through
several car radios. The AM only where much more sensitive than the AM/FM
combinations.

4617. Land Mobile Radio FAQ needs your input!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-09 00:00:00 UTC
From: randolph@est.enet.dec.com
Message-ID: <45bbhi$29s@mrnews.mro.dec.com>
Source record: 110317
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

The Land Mobile Radio FAQ is now under way... I need your support!

What is it?

A listing of those surplus police and taxicab radios from the various manufacturers, how to identify them, what band they're on, how easy it is to tweak them into the ham bands, average price used, etc., all in one file for your flea market shopping convenience!

What it's not is a mod manual. You won't find out HOW to do the mods in the FAQ. That's up to you. You will find out where to get the manufacturer's manuals, most of which have detailed tuning procedures. Some of the radios can only be programmed by the manufacturer, and/or by using the manufacturer's proprietary software. Such details will be in the FAQ.

I'd like to include any and all mobile or handheld radios aimed at the commercial or public service market. Many of these out-perform the imported synthesized units by a long shot, are cheaper, and make great ham rigs! Let's put these great radios back to work and on the air!

I NEED YOUR INPUT TO MAKE THIS A REALITY!

You don't need to mail me manuals or anything like that, unless you WANT to. All I ask is a few bits of data for any of these radios you or your friends may have worked on in the past. If you've put one on the air, you've had to answer these questions, so fill 'em out and send 'em in!

Model? Manufacturer, model name (like Mastr II, Syntor, Delta, etc.), model number

Band? These radios are usually made for use in a specific band of frequencies, like 30-50 MHz, 150-170 MHz, 450-470 MHz, etc.

Freq control? Crystal, synthesized/ROM programmed, synthesized/microprocessor programmed

Average price? What did you pay? What prices did you see when shopping? New or used?

Manual price? How much did the manual cost?

Mod difficulty? How hard was it to get it tuned to ham band?
Easy: re-crystal, tweak a few tuning screws
Difficult: program a new ROM, swap a few parts
Extremely difficult: Major modification and re-design of some circuits, you must pay

authorized technician to use
manufacturer's software

How to indentify? What details do you need to know to tell these radios
apart? Does the serial number tell you anything? Does
the Model number? Are there physical differences?
This is the stuff you need to know when sorting
through the radios at the flea markets. This
information is usually in the manufacturer's manuals
in great detail.

I will re-post this notice about every other week for a while, until the FAQ
is somewhat filled out.

My net address is: randolph@est.enet.dec.com
All information, network pointers, periodical references, anything, is
appreciated, and thanks in advance!

-Tom R. N1OOQ randolph@est.enet.dec.com

Hi Paul;

I'm planning to use a pair of 6146's as an amplifier for an old CE-20A SSB Exciter I bought at a hamfest last Saturday. I also bought two carcasses of old SB-400 and SB-401 transmitters. In both units the finals, driver stages and power supplies appear complete, although the units had been stripped of most other valuable parts. Should be able to make a dandy amplifier for the old 20A.

I guess I'm doing it the lazy way instead of building the whole thing from scratch. At the same hamfest I saw a carcass of a Yaseau FT-101 available for $5. The owner said the power transformer was good too! In retrospect, I probably should have bought it too. ;-)

Good luck,
Bill, N5BU

Source record: 110321

I am in need of some help diagnosing a problem with my Pyramid PS-50 power supply. It is an adjustable 12-15 volt supply capable of about 50 amps. It's about 4 years old.

Here's the problem. When it's first turned on (after sitting for several hours) the voltage will rise to the proper level then immediately (10 - 15 seconds) start to drop off. It will eventually platuea at about 7 or 8 volts. If you turn it off and then cycle it back on immediately then the voltage never does rise to a normal level, it just starts low and stays low.

Here's what I have tried as fixes. It has a 732 voltage regulator chip and I have replaced it. No change. I also changed the 2N3055 regulating transistor which seems to somehow control the other six 2N3771 power transistors. No change.

I am at loss about what to do next. Could it possibly be a filter capacitor (five of them 10,000uf / 25 v)?? Or maybe the transformer? Or maybe one of the six (2N3771) power transistors? All of the parts are available through Digi-K ey and I am willing to replace them myself, but I don't want to have to take the shotgun approach and replace everything until it starts working. I'd prefer to have a more educated guess.

Thanks in advance for your help.

...
>Terry Fugate

That's correct Terry, The input of an AM car radio is usually a very hi z bridging input, because the antenna is a hi z voltage probe. It's nowhere near the impedance of the line feeding the antenna, and nowhere near 50 or 100 ohms.

The suggestion of a load resistor is excellent. If it detunes the input of the radio and causes problems he could load the converter with a low z load, and bridge the RX in with a low value cap.

Source record: 110233

A voltage regulator works by developing an error signal derived from the diference between a voltage reference (usually a zener diode) and some fraction of the supply output voltage, derived from a voltage divider. One possible explanation of your problem is that the zener or the voltage divider components are changing value with temperature.

The fact that it starts low and stays low when you turn it off and on after a failure suggests a problem with the current overload circuit. Many supplies have a "foldback" current limit that takes the output voltage low when it thinks the current limit is exceeded. I didn't notice if yopu mentioned the load conditions for the failure.

it would be helpful if you had a schematic. The you could go through with a voltmeter and try to get more information.

Good luck,

Jim

The Cascade was produced earlier this last year by the NorCal QRP Club. I am not sure if you can still get one from the "first" run. Orders had to be in by last June. I don't know what the future holds for the rig, but I have the following info for you and any others:

The Cascade was designed by John Liebenrood, K7RO. And only one run was planned. John may make them available again through a commercial company {See below}.
John Liebenrood, K7RO
1650 NW 130 AVE
PORTLAND, OR 97229

Two earlier 'projects' by the NorCal QRP Club are now produced by a new company started by Bob Dyer, KD6VIO. The company is known as:

Wilderness Radio
P.O. Box 734
Los Altos, CA 94023-0734
(415) 494-3806

They have the NorCal 40A and the multiband CW transceiver called the NorCal Sierra. Both are QRP kits. They may be offering the Cascade sometime.

The last resort would be to contact:

Jim Cates, WA6GER
3241 EASTWOOD RD
SACRAMENTO, CA 95821

Jim will probably know about the status of the Cascade. Also if anyone would like join the NorCal QRP Club and get the journal of the NorCal QRP Club known as 'QRPp' which discusses these radios, etc. and is published professionally four times a year, contact Jim at the above address. If you would like to call him you can E-mail me for the phone number.

Also, the NorCal QRP Club will meet and display all kinds of QRP
kits and equipment at:

Pacificon '95 Amateur Radio Convention
October 20, 21 & 22
Concord Hilton Hotel
Concord California
For more info: (510) 932-6125

Good luck!

writes:
>Anyone know impedance of AM car radio antenna input ?, is it 50 ohms ?.
>I am designing a convertor and can not find info I need .

Generally the impedance of an AM/FM car radio is about 75 ohms.
Impedance of the "old" AM only radios (transistor) was also about 75
ohms. The really old (tube) AM radios had an impedance of between
75 and about 95 ohms.

Radio Shack has a couple of experimenter's books, and I'm pretty sure
they ALL show how to use a 555 timer IC as a free-running oscillator.

This is about as easy as it gets. As I recall, you'll need the IC, a 9V
battery, a speaker, two resistors and two capacitors. Key the Vcc
for cheapest results.

They used to sell a straight key with an audio oscillator, as a Morse
practice set -- but I thought you might like to build something....

There's no need to guess, and there's no need for shotgunning.
Troubleshoot the supply, find the defective component, and
replace it. Take a systematic approach. A divide and conquer
binary search is a good plan. First take a voltage reading
across the filter capacitors. It should be between 16 and
18 volts with no more than a volt of AC ripple (should be
less). If that's Ok, then the problem is in the regulator
circuit.

If the voltage across the filters is low, or has excessive ripple,
then the problem is either an open filter, a bad rectifier diode,
or a bad transformer. Read the AC voltage across the transformer
secondary. It should be 14-16 volts AC or a little more. If it's
less, then disconnect the wires going to the rectifier bridge
and measure the secondary again. If it's still low, check the
voltage across the primary (careful 110 volts AC here). If that's
Ok, then the transformer is bad. If the 110 is low, look for
an ohmic fuse or switch in the primary circuit.

Now lets assume that the transformer secondary voltage is good
when disconnected from the bridge. The most likely culprit is
a shorted bridge diode. Check them with the ohmmeter. You should

measure a good front to back ratio on the diode test scale of
a DVM, or see a marked difference in forward and backward ohms
readings with an analog meter on a low ohms scale. If you find
a diode that reads the same both ways, it's probably bad, but
you have to take it out of circuit to be sure. If it reads
the same both ways out of circuit, it *is* bad. (Be sure you
know how to identify the leads of a diode bridge package so
that you really are reading the individual diodes.)

Ok, now lets assume you had a good secondary voltage reading
and the diode bridge is good. If the voltage across the filter
capacitors reads low, and/or has lots of AC ripple, then a filter
capacitor is probably bad. Power supply filters *can* fail shorted,
but you'll usually notice that from the spewed electrolyte and
the bad smell, so we'll assume the filter has failed open.

Here's a quick and nasty way to test a filter capacitor. Disconnect
the load side from the capacitor, turn on the supply and let the
capacitor charge (less than a second should be long enough), turn
off the supply, and short the capacitor with a clip lead or a
screwdriver (directly across its terminals, *not* to "ground".
A spark should jump. If it doesn't, the capacitor is probably open.
(Note: there are *lots* of caveats to this quick and dirty test,
but it should be safe enough in this case at this voltage. Don't do
stupid things like trying to short the filter with the power supply
still on, and that spark should be *hot*, so don't burn yourself,
short it while holding only an *insulated* part of the tool.)

The preferred method is to use a capacitor tester, or to use judgement
and experience with an analog ohmmeter, looking for a "kick" after
you've charged the capacitor with the meter in one direction and
quickly reversed the leads of the meter. It takes experience to know
how much "kick" signifies a good capacitor. The spark test is almost
surefire.

If there are several capacitors in parallel as there are here, you'll
have to test each one separately, *out of circuit*, otherwise you won't
know which one(s) is/are at fault.

Ok, lets assume you found a good voltage at the filters, so now
you know the problem is in the regulator circuit. This is a simple
pass regulator, so the base drive to the 2N3771s should be about
0.6 volts higher than the desired output voltage. Measure between
supply negative and the base of any of the 2N3771s and see if you've
got 14.4 volts at the transistor base. Since you've already replaced
the voltage regulator IC, and since you've swapped out the 2N3055
driver transistor, we can assume that they aren't a problem. So
if you get a low base voltage reading on the 2N3771s you need to
back up and look at the reference voltage to the IC, you may have
a bad resistor in the reference circuit, or one of the little
electrolytics in that circuit has gone South. If you get here,
come back for more help.

Ok, lets assume that you had good base drive voltage on the 2N3771s but that the output voltage under load is still low. That probably means one or more of the 2N3771s is bad. Pull each out of circuit and check it. You can do that with a transistor checker, or with an analog ohmmeter, or a DVM with a diode test scale. If you don't know how to test a transistor with an ohmmeter, speak up, and we'll tell you how.

If all the transistors check good, check their current equalizing resistors. One or more may be open.

At this point, you should have found the bad component, and all you have left to do is replace it.

A 555 timer chip running in astable mode will get you the tone, though it may be a touch raspy. Or you could wire up a Twin-Tee transistor audio oscillator if you are a purist. Circuits in the Handbook. But if you aren't so picky about the tone frequency, then just go to Rat Shack and get a piezo buzzer. Key the B+ and instant code practice oscillator.

You can poke around with a volt meter to help isolate the problem
(as long as there is no smoke pouring out). To see if it is the
transformer, measure the stored voltage on the secondary filter caps
and make sure they are above 15V.

If something is getting very hot, it may be sucking the current out.
You can usually hear buzzing sounds if a lot of current is going
somewhere.

Check the base voltage of the pass transistors and see if it is in
the 12.5V+ range. If it is too low, then the drive to it is suspect.
I don't know how this PS works, but it sounds like a linear regulator
that uses a 3 terminal regulator to control pass transistors. If too
much current is taken from the 3 terminal regulator, it will shut down
in a way similar to what you describe.

Hope this helps,

Jim Goecks

Can anyone please help me?

On the weekend of October 21st the Scout movement is involved in the Jamboree On The Air (JOTA). We at the Phoenix Venture Unit (Kenton & Kingsbury District) North West London, had arranged for a licenced radio operater an a few of his collegues to use our Unit Den as a base for a radio station. We have made all the arrangements for masts and wires to be strung for aerials telephone lines etc. but he has just been given the completion date for moving house and it is that weekend, therefore we are without a licenced operator. Is there anybody or a radio group that would like a change of venue with opportunities for new contacts that would be willing to help us out, time is of the essence with regard to arrangements and licences etc. If you can help or require any further details please reply asap.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
October 15th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Has anyone seen successful application of muffin fans as a cooling source for the 3-1000 ? I realize that one might need a larger size fan. Since the 3-500Z tube likes this method and the 3-1000 is just a bigger version I thought the same methods would work - that is raising the socket slightly to cool the pins, etc. Blowers take a lot of room...

There's a nice solid state amplifier in the 1986 ARRL Handbook. I have a Truckers AMP that is almost identical, and used it to get my 10m rig into the 100 watt range. Should be easy to duplicate.

But if you're interested I have a nice tube amp that will fit the bill, I think it's a 100 watts out for 4 watts in. Now that I have a real HF rig, I don't need this converter stuff :-)

>While I'm on the subject, can someone enlighten me about what is and is not
>legal to transmit in the FM band in the U.S.?

Most of the chip Stereo transmitters don't have good audio quality. You
should be able to transmit anything you like. You can even transmit stereo
in the ham bands if you want. The city library should be visited to learn all
the regulations under Part 15. It mostly regulates power, not content. You
can't cause interference of course. If you decide to broadcast phone sex,
then that probably wouldn't be allowed. There are limits to everything.

I don't know of any schematics, but you probably want to start with the RF
section and work back. You need a very linear, high bandwidth capable
transistor. Otherwise all that quality audio before it goes right into the
dumpster.

Anyone know of a good choice?

4645. Re: Crystals in cordless phone

In a previous article, calhoun@gorge.net (Dave Calhoun) says:

>How do you retune a pilot tone? Thanks for the reply,
>dave

Dave:
First of all, make sure that everything else is working on the phone before you try this. Confirm that the phone is transmitting on both the base and handset. This can be done most easily with the help of a programmable scanner.
Second, confirm that the recievers are working on both the base and handset. Best thing to do there is to use a scope and go in on the IF/ decoder IC and probe around for white noise on the hand held portion while the base has no power applied to it and the base when the hand held is shut off. Then, turn on the unit when you find it and see if you see the white noise quiet down and possible look for audio when either the handset is talked into on the base or on the handset when the page or intercom button is pressed. If you dont have a page or intercom on the base unit, then look for quieting on the handset and leave it at that.
If you have all of this and your phone does not work, then and only then you may need to adjust the pilot tone. If you adjust anything in a phone be sure to note the position on the pots inside either the base or handset. Go thru the phone and determine what does what. For examble in the handset there will be a pot for deviation and earphone volume as well in some phones for compression. If you have one of the secure phones then there may be more adjustments (I have yet to run into one of these). Once you feel that you have found the adjustment pot for the pilot, say in the handest, note where it is and adjust with the base unit powered up and connected to the phone line, antenna fully collapsed on the handset and base and at least 10 feet away from the base but not more than 50 feet. Adjust slowly and see if you can bring up a dialtone. If you cannot, reset the pot back where it was and move on.
Now Dave I am assuming that you know a little bit about transmitters and recievers and that you know a pot from a coil. If you have a schematic great but you probably don't. This takes a lot of thought in understanding some of the workings of the cordless phone and where some of the controls are in one of these units.
I have mostly experimented with cordless phones including a whole boxfull that I recently picked up at a hamfest. I do not fix cordless phones for a living and just find them interesting devices so I am not a expert.
If you wish to write me direct, feel free to do so. I posted this so that others might be interested and post a reply on this. I might have missed something (very possible) or have a hint that may aid you in repair.
Good luck Dave

Source record: 110255

Ham Radio published a short article on using the 4CX250-series
tubes withOUT forced air cooling. Used a loctal socket
instead of a Eimac mondo-dollar socket. Sep. 76?? I don't have
the reference handy, but I have a photocopy of the article.

Seems this tube works nicely to about 80 watts plate dissipation without
requiring any forced air cooling, just plenty of room for convection.
I don't recall if this was grounded-grid, but it wanted to see about
5 watts input for about 100 watts out on SSB. They tested on 20m,
but a 10m network for this tube is trivial.

Power supply was from an old TV set transformer and gave about 800 V Ep
and provided filament for the final as well. Pi network output,
untuned input. It was so simple I don't know why it never made
the Handbook -- oh, wait, maybe I just figured it out.

The best part of this amp was that if you used the right socket and chimney
you could provide forced-air cooling, and QRO by simply providing a
hotter plate supply.

Ok, here's a newbie question for today.

The November 1995 Popular Electronics has a pretty neat project I want to build. The project is a 1/4 wave ground plane antenna. The main component in the antenna is an SO-239 panel mount connector. The author of the article claims that the connector must be silver plated as nickel plating will not work. Why? I am having a devil of a time finding silver plated SO-239 connectors in Phoenix, but can get nickel plated for $5.00 at Radio Shack. The author does not explain why he feels that only silver will work and I have no clue. Thanks in advance for any help.

tgoins@accessone.com (Todd Goins) is trying to fix
a commercial power supply that uses a 723 voltage
regulator and a bunch of pass transistors.

jgoecks <jgoecks@pacifier.com> responded with some help
but added that "it sounds like a linear regulator that
uses a 3 terminal regulator to control pass transistors".

I just want to point out that the 723 IS NOT a 3-terminal
regulator. The 723 is actually a much more complicated
voltage regulator IC. It comes in a TO-5 package with10
pins, or a 14pin DIP. I seem to recall that it predates
3-terminal regulators. It is a quite common IC; probably
made by many different manufacturers. I know National made
it, and I would assume they still do. By itself, it can
supply only 150mA of output current. It was intended for use
with an external pass transistor. Probably in the very early
days it saw use as a low current regulator without pass transistor,
but ever since 3-terminal regulators hit the scene there's no
sense using the 723 for low current applications since it
requires external parts. On the other hand, since you can
do things with those external components to change it's operation
(there's little that you can do to a 3-terminal regulator), the
723 can be used for quite a few different things.

It is worth having the data sheet for the 723, since you may
come across it in circuits. Certainly if you are servicing a supply
that has one, it's worth getting the data sheet. If you don't have
a schematic, it's a whole lot easier to figure out the circuit by
comparing the circuit on the board with the "standards" in the data
sheet than to trace out the circuit on the board and then try to
figure out how it works.

4654. Motorola Engineering Brief Help Needed!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-13 00:00:00 UTC
From: jason goldring <jason.goldring@sheridanc.on.ca>
Message-ID: <DGEJEB.EH1@eclipse.sheridanc.on.ca>
Source record: 110125

I recently aquired Motorola Engineering Brief number 63, which is a 140 watt 2-30 Mhz Broadband RF Amplifier, which is built around the MRF454's.

After waiting patiently to get a hold of an engineer at Motorola regarding the substitution of RF devices in this circuit, I was told that the MRF455 could be substituted for the MRF454. (The 454 is a hard part to get around here, but the 455 is readily available.)

My problem is that when I connect power to the unit, the transistors get hot very quickly, and my meter shows a current draw of 11 amps. I have gone over my wiring several times, and I have tested every single part for defects, and everything is ok. There are no shorts to ground. According to the engineering brief, the unit is supposed to draw only 500 ma. max per transistor during idle periods, and I am wondering if something has to be changed on the circuit board to allow the 455's to run properly, rather than drawing tons of current like it does now. Does anyone have any ideas? I get a feeling it has something to do with the bias resistor, which is a 33 ohm 5 watt wirewound unit, which feeds directly to the base of both transistors. Maybe the value has to be changed??

Any information would be greatly appreciated!!.

Trying to replace a multiplied-up crystal oscillator with a simple
minded synthesizer consisting of a '157 and VCO is asking for trouble
with spurious sidebands. Unless you really need a lot frequency
agility, you would be far better off negotiating a group purchase
of crystals by the club. This is one of those projects where anyone
who knows enough about the technology to know what is involved wouldn't
want to do it. (BTW, if you "want to learn about synthesizers", pick
an easier neophyte project).

If you're using a wirewound bias resistor, I hope it is well isolated for RF from the rest of the circuit, otherwise the inductance may be causing a parasitic oscillation, which could explain the high current!

Replace the 33 ohm bias resistor with a NON-INDUCTIVE unit (what the
other poster said).

I built one of these amps some years ago and used a 2-watt carbon resistor,
raised about 3/4 inch off the PCB. It worked fine.

Although it probably wasn't necessary, I added a couple of slip-on round
aluminum heatsinks, w/ heatsink compound, on the body of the resistor.
They were loose enough to slip and slide, so I doubt they gave any added heat dissipation.

The resistor never discolored, so it was well within its power range.

This is the cheap way. I think Vishay now owns Carborundum, who makes
leaded non-inductive resistors. You can also get planar thick-film
non-inductive resistors (they look like a TO-220 transistor with 2 leads)
but I don't have a source. Both these are expensive.

In a pinch you could substitute a bunch of paralleled 1/2 W resistors.
Since you're building a CB lee-nyar amplifier, I'll leave the determination
of values to you.

good luck, you're on the right track.

I've seen other versions of the article (the same antenna plan has been published in *every* electronics magazine I've looked at sometime in the last 6 months), the "author" recommends little nuts & bolts through the flange holes to attach the ground-plane elements. Gary's suggestion of scraping down to brass sounds better if you don't plan to give it routine maintenance...

The Radioshack antenna book has a tri-band version of this groundplane; it hangs two L-shaped hooks on the main radiator to tune it to two other bands (one at the base and another at a "node" up the main radiator).

I was thinking of trying one of these but replacing the ground-radials with a miniature actual ground plane. I've got a bulkhead BNC feedthrough that I'm going to install in a pie-plate. The pie-plat won't be a tuned ground-wire, but it also won't poke me & will provide better near-field shielding: I'm going to mount it on a pack-frame (with an adjustable lift) for either/both/one-each my HT and cell-phone. I got the idea from someone who said they used a magmount rubber-ducky antenna on the dinning room table with a pie-plate.

I take a 100W iron and acid flux to the nickel plated connectors and
tin them in advance, where I want to solder them later. This works
quite well with plugs too - tin the whole interior where the braid will be
soldered. You might want to connect the mating fitting to hold the
pin/socket in place, if the dielectric is not teflon. [I have another
trick for plugs, but this isn't the place...]

>will not work. Why? I

Hi,

Quite simply the answer is, that the author does not know, what he is talking about. Surely the silver plated connector has less loss, but the major concern is the plug that will mate with the connector. Unless you know pretty well how to do it, there is only little chance to mount the cable to the plug without substantial losses.

My suggestion is to ise a N-typt connector if the cable is thick (RG213) or a BNC connector, if the cable is thinn enough.

The Ramsey Kit Model FM10A does what you need. The price is about $35.
for the board and parts.

I am not sure what the comments about linearity are all about. We are
talking about an FM transmitter here - unless you are talking about
voltage vs. frequency linearity of the FM modulator. Amplitude linearity
is not a factor for the oscillator transistor.

I'll disagree with a little bit of that. The capacitance per foot of the feedline MUST be low, because the antenna is so short. So the feedline length isn't as important as the total feedline capacitance, since it shunts the antenna. That's why in the days when AM reception was paramount, the feeder had a single teeny tiny hair like conductor in a mostly air insulated cable.

An earlier statement that said "adding a few feet of regular 50 or 75 ohm cable will kill AM sensitivity" is very true. It becomes a capacitance voltage division problem. The input of a standard WELL DESIGNED car radio is a very high impedance, and the feedline of a WELL DESIGNED AM system is very low capacitance cable, because the AM antenna is a very high source impedance voltage probe.

If you use this tube be aware that the self neutralizing frequency is very low, so you need very short grounds from the grid pins to the chassis and a very short anode to chassis connection through the plate tuning cap. So elevating the socket may mess up the performance!

A 3-1000A also usually requires a special parallel resonant parasitic choke to stabilize the amp without excessive loss on ten meters or 15 meters.

You can cool the tube with big muffin fans, the back pressure is low. But be sure you use temperature sensitive paint or crayons to check the seal temps if you homebrew a non-standard cooling system. Remember that tube is exactly like a 1000 watt electric heater, and it takes a good volume of properly directed air to keep it cool. Muffin fans "puffing across the tube" will be noisier than a blower or pressurized airflow system for the same amount of cooling.

Good question. The silver version would be easier to solder to. I
would say, make sure the dialectric inside was Teflon as the connector
will probably get fairly hot during soldering and Teflon doesn't melt
too easy. Often but not always, you can only get Teflon dialectric
SO-239's if you buy the silver plated ones. 73, John

Good point. In one of National Semiconductor's data books (linear data book?) there is a very good technical analysis of auto radio AM broadcast band antennas complete with math. One interesting point they made was that the auto radio antenna is far more efficient than the ferrite rods typical of portables and table radios. But then again, you can peak or null signals with a ferrite rod. So the table radio probably has potential for better signal/noise ratio but in the absence of interference the whip is a better choice for weak signal reception. Hard core AM DXers often use a combination of open loop and whip "sense" antenna. The combination can be tuned for a cardioid type pattern.

I would suspect that silver was specified over nickel due to outdoor
application. The silver will give better conductivity over nickel when
corrosion occurs. However when you do put dissimilar metals together, galvanic
corrosion can exist at the interface. This would be dependent upon the two
metals and their respective positions in an electonegativity series.

Two dissimilar metals can also form a simple diode circuit. It would not be
unusual to get rf rectification off such an interface with subsequent tvi.
We do have a tendency to get hung up on the details and loose sight of the big
picture. I suspect the rest of the antenna is not silver plated so why worry
about dissimilar metals ???

My reccommendation is go with the Nickel and adequately weatherproof the
installation which is simply good engineering practice anyway. If you don't
get good results, don't be surprised if silver doesn't work any better.

>My suggestion is to ise a N-typt connector if the cable is thick (RG213)
>or a BNC connector, if the cable is thinn enough.

Absolutely. 239-type connectors are not too good at either maintaining a
good connection or handling high frequencies. Their only "advantage" is
low cost. Especially at 800 MHz, N or BNC connectors should be used,
depending on the size of the cable to be used (which should be large if it
is more than a few feet long).

If this is one of those 1/4 wave pyramid-like antennas, the author probably
specified a silver connector because it is easier to solder the radial
wires on. A connector with a Teflon center insulator is pretty much
essential for this as well as the other plastics tend to melt under
moderate heat. The least expensive (Radio Shack grade) connectors are made
of plated zinc or brass; if you file the plating off the base metal
underneath can be soldered, but there may be problems with the insulator
melting. Some of the mid-grade ones are nickel (or stainless?) throughout
and difficult to solder, even if filed. The author may have had a bad
experience with one of those. Silver or gold plated connectors are easiest
to solder and usually have the Teflon insulator. Since an 800 MHz 1/4 wave
antenna is quite small, a gold-plated SMA may be a viable choice.

When soldering the radials on, it works best to heat the connector up first
and tin it, flowing solder around and through the holes. Even with a
Teflon insulator, be careful not to overheat it. A 100 Watt solder gun is
barely adequate. If you use a torch do it carefully, keeping the flame

only on the flange of the connector and not the center where it could damage the insulator. After the connector is prepared, tin the ends of the radial wires. Then re-melt the solder on the connector one hole at a time and join the radials on. Careful heating is again required so only one corner of the connector is hot enough to melt, but at the same time the joint is not 'cold'. If that seems impossible to do, some sort of jig could be built to hold the radial wires in place while all the solder is melted.

If the antenna is to be used outdoors, be sure to seal up the top side of the connector (unless you have found a hermetically sealed military one) and cable attachment to keep water out. Silicone sealant should work for this, though it may detune the antenna slightly. It's also a good idea to remove all solder flux before sealing.

This is probably entirely too many words about such a simple subject. At the same time, I've undoubtably left out much essential information. Do I qualify to write a magazine article yet?

Actually, the author is probably concerned that the nickel plated
chassis fitting won't take solder well in the flange holes (for
the groundplane elements). Nickel plate is a pain in the a** to
get to take solder. Silver, OTOH, takes solder nicely.

However, if all you can find is nickel plated fittings, all is not
lost. Just file that blankety-blank plating off and the brass underneath
will take solder easily.

>an easier neophyte project).

Though I don't claim to hold a candle to Rick's experience, I have
a couple of comments. I essentially agree with him; synthesizing
at a lower frequency and multiplying up is asking for trouble with
reference sidebands. The problem is, the '157 is limited to around

15 or 16MHz (lemme guess; the radios use rocks multiplied by 3, and therefore look reasonable for the '157 to synthesize). Suppose you have a x3 chain after your transmit oscillator; to get a 5KHz channel spacing, you need to run the PLL with a reference of 5KHz/3, or about 1700Hz. Getting adequate suppression of this reference component in the output of the phase detector will be a pain in the butt, not to mention the PLL will likely take a lot longer to lock up than you really want. So, you _could_ use an adaptive loop filter to widen the PLL loop bandwidth until you start to detect lock and then narrow it considerably, but you'll never be happy with it.

If you're willing to select another PLL chip, I suspect you can get better results. To start with, I suggest you select a PLL that can synthesize directly on frequency; the MC145170 immediately springs to mind, this chip is good to at least 160MHz (and it is easier to program than the '157). Using a '170, you could run the VCO at the 1/3 frequency and take the feedback frequency from the multiplier chain after it has been multiplied to on frequency. Here, your reference is whatever the desired channel spacing is, say 5KHz. There's something else that happens that you may not expect, though; the reference sidebands will be at 5KHz intervals at the VCO output which is then multiplied by 3. You'll have a radio with a 5KHz reference PLL but the transmitted reference sidebands will be at 15KHz intervals! If you can do a decent job of suppressing them in the loop filter, they may not be objectionable in the transmitter output and will be outside the passband of most receivers; your synth won't exhibit the 5KHz whine that virtually every Japanese FM radio does today. You'll have a 15KHz whine but no one will normally here it. The risk is that these sidebands will cause more interference to adjacent channel users than you want to live with.

With all this said, Rick is right; buy the crystals. You see, even if you build a PLL that generates a decent carrier, you've still got to modulate it. If the radio is a phase modulated type, this isn't a problem, it would just work. However, if this is a radio that modulates the rock, you'll have to develop a VCO with decent linearity and reasonably constant modulation sensitivity across the band. This isn't easy at all.

If you have some '157s, build a few 10-15MHz synthesizers and experiment with loop filters, if you haven't already. It is novel to see that the reference sidebands are clearly there when tuning around on your HF receiver, and it is novel to hear the PLL bounce onto frequency.

Take care!

This is absolutely wrong! If it were true, you would never be able to
accomplish voice modulation at the rock frequency then multiply up. The
voice sidebands, by this argument, would be spaced 3x apart from where
they should be! Clearly, this doesn't happen.
What really would happen is that the incidental modulation from the 1700
hz sidebands would be 3x as great at the output frequency as it was
coming out of the synthesizer. 1700 hz is a workable reference frequency
for x3 post multiplication... you just have to be careful with the loop
filtering. It's done all the time. If you want the 1700 hz whine at the
output frequency to be 40db down, then it has to 50 db down at the
Fo/3 input frequency.

This is partially true. If the radio employed phase modulation of the
crystal oscillator output, then it will modulate the synthesizer output
equally well...a CW carrier is a CW carrier - the modulator doesn't know
where it came from. On the other hand, if the radio modulated the
oscillator directly by 'pulling' the crystal, then you'll have to put the
modulation audio into the VCO. This is easily done by using an op-amp
mixer to AC couple the modulation into the DC contol voltage.
There are also plenty of other clever ways to get the same result. The
important goal is that the coupling must not upset the bandwidth and
performance of the loop filter.
Practically any VCO you build will have plenty of linearity to allow +/-
1.6 Khz of deviation.If you want a VCO design that will cover up to an

octave tuning range and is virtually foolproof, E-mail me. The real trick will not be getting the synthesizer to work properly, but in solving the subtle problems related to driving the radio properly. Of course, you'll never get more of an agile range than the radio tuned circuits are designed for, but you can become independent of pesky crystals over the limited design range of the radio.

4678. Ic-245 Schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-14 00:00:00 UTC
From: n0nas@hamlink.mn.org
Message-ID: <813655270.AA03883@hamlink.mn.org>
Source record: 110138

I have an old Icom IC-245 2 meter FM rig with an AM/SSB adaptor.
Last week the LED frequency display went dark and it hasn't come
back on. This naturally makes it difficult to tell what frequency
I'm on or if the radio even happens to be working.
.
I took it apart and found someone had already been soldering jumper
wires on the PLL board. Makes it sound like this radio previously
exhibited similar difficulties. I've seen several old Icom's that
had problems because of the lousy solder joints on the rivets they
used to connect traces on the double sided board.
.
Since this is the only SSB rig I have access to, I'd like to fix
it but don't have any schematic or documentation at all. I tried
our local ham radio store but their service dept had no manual.
If you have a service manual or schematic for this radio, please
send me email and let me know what it will cost to get a copy.
If you have access to a FAX machine, you could FAX it to me at
work. Just be sure to put my name on the cover sheet.
Thanks for your help.

73's.

Years ago, the input impedance for auto radios was designed for
600 ohms. That was prior to FM being included as a standard
feature. But I seem to recall that it has not changed, for several
reasons.

I remember, as a teenager, taking an off the shelf AM wireless microphone kit (one transistor) and adding more C to lower the frequency to 455KHz. It worked fine as a BFO. Just placing it close to the receiver with no direct connection worked fine.

The problem you will have with the Transoceanic is that it tunes such a wide frequency range over such a small dial span that the stability is probably not there for CW or SSB reception. It might be difficult, if not impossible, to use the radio for that purpose.

In the "good ol' days" back in 1960 something, we used to acquire aluminum transcription disks
from radio and TV stations and use them for ground planes for two meter verticals. As I recall, these were about 16" in diameter with a hole in the middle that could be enlarged for
a (gasp) SO-239. These were ALL silver-plated in those days <g>. I even used one as a GP in my
1956 Corvette (how I wish I had that back, sigh)

Hey all,
I'm tossing around the idea of buiding a desktop microphone for my radios. Radio Shack sells a fairly inexpensive mike that is unidirectional (seems like a good idea in this application) and is mounted on its own gooseneck. The only signifigant drawback is that it is fed with 3-wire "balanced" line. (This is how Radio Shack describes it.)
My question is: In this context, does balanced mean the same thing as when refering to antenna feedline. If so, what is the third wire for? Does the mike need a DC bias? Also, can I just use a regular balun to convert it back to two wire, unbalanced feed? (R.S. sells adaptors, but they're $14.)

Thanks,
Ross

Although in this case it does not apply...

There is some Mil-spec that I haven't memorized ;) deeming that only silver plated connectors will be used at uhf frequencies. The iron content of the nickel plate causes some magnetic problems.
Can some clear this up? I cannot recall the source or the details.

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Jeff, k9ja

Do you know which copy of qst this was in??? I'm about 95% of the way
through builing my ramsey kit and this does not make me happy to read!

yes and no...

>If so, what is the third wire for?

the 3rd wire is a ground

> Does the
> mike need a DC bias?

no DC bias is needed

> Also, can I just use a regular balun to convert it back
> to two wire, unbalanced feed? (R.S. sells adaptors, but they're $14.)

I'm not sure what a 'regular' balun would be, but nothing of the sort is needed here. all that is meant by balanced in this case is that neither of the audio lines from the mic element is grounded, and both are available at the connector. the 3rd wire is to ground the case of the mic.

all you need to do is connect one of the two audio leads to the ground and the mic is now unbalanced. don't buy the RS adapters for $14 they are really crap and you're paying mostly for the hardware, not the transformer inside.

the only other area of concern would be impedence matching, which should be easy to take care of...

Ross,

The other comments in this thread have pretty well covered the issue, but I just wanted to mention one thing.

The purpose of balanced microphone designs is to eliminate hum that could otherwise result from common mode voltage being picked up on the shield of an unbalanced system.

This isn't at all likely to be a problem in the typical ham shack, so connecting the "Low" side to ground is an acceptable alternative to purchasing a balanced to unbalanced adaptor.

73,

Jack WB3U

4695. Remote mounting RFI ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-15 00:00:00 UTC
From: hduff@humnet.humberc.on.ca
Message-ID: <8015208463501@humnet.humberc.on.ca>
Source record: 110155

I'm in the process of adding a synthesizer to a GE lowband mobile radio
to eliminate the need for 6M crystals. This may lead to a club project
since we have aquired a few skids of these radios, one for each member.
These radios are trunk mounted with a remote head. The synthesizer
consisting of a small single chip micro to program the serial interfaced
PLL chip will be located inside the radio chassis. Channel selection
will be done from a switch located of course at the head (on the car
dashboard). The distance from the head to the radio in the trunk will be
roughly 10 - 15 feet.

I am wondering if RFI from the engine might play havok with the channel
selection lines that lead into the synthesizer micro ? It was suggested
to me that I consider some means of protection on the channel select
lines since the micro may be vulerable to noise (other than simple
bypass caps to ground). My dilema is in trying to keep the design as simple
as possible with minimal parts count, I'd prefer to avoid the extra
hardware if not essential. I observed that some of my other commercially
made Ham gear which is remote mounted uses a 4 wire interface
(pwr/gnd/rx/tx) that runs between the trunk mounted main chassis and the
head. The wiring runs directly from one micro in the head to another micro
in the main chassis (no buffering or protection) and it seems to work just
fine. Should I assume that RFI will not be a problem or should I practice
good design technics and incorporate some protection ?
I presume that running the same wiring through the engine compartment
would definitely require some protection but since I'm going the
other way and further away from the noise that it should not be a real
problem.

Any comments/suggestions welcome.

Thanks..Hugh Duff VA3TO Toronto

>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com
>

Hmm... Jumping to conclusions ? Did I say anywhere that the frequencies
that I would synthesize would be at the crystal fundamentals ?

"This is one of those projects where anyone who knows enough about the
technology to know what is involved" ...would know that bypassing the
multiplication stages in the radio and just generating the highest
and closest to the operating frequency with the PLL/VCO would be best
approach (which IS indeed the way it is going to be done).
I'm operating the PLL/VCO at half the required frequency and running it
through 1 doubler stage within the radio. The doubled frequency runs
through a bandpass filter, spurs are not an big issue.

You might want to brush up on your personability skills...
"...simple minded synthesizer..." and your approach in general ceratinly
don't contribute positively to the spirit of homebrewing !

>
>Does anyone know where I can find the design for a s/n+dist. measuring
>instrument?
>
>Such a device was made by a US company many years ago, and named a
>"SINADDER3".

You will need to build a sine wave oscillator and a sharp null filter
to match the frequency of the oscillator. Shoot for about 1 KHz.

The oscillator modulates a signal generator that supplies the
receiver with a test signal. The output of the receiver is connected to
the filter and then to an AC voltmeter.

The voltmeter is used to measure the noise at the receiver output.
The filter can be switched in and out of the circuit.

With the filter switched out, you can measure signal+noise+distortion
and that becomes one of the reference points for the db measurement. With
the filter switched in, you're measuring noise+distortion only and that
becomes the second reference point.

There are quite a few different schematics for oscillators and
filters. Pick one that matches the contents of your junk box or is
easiest for you to understand and get working. There's nothing much to go
wrong. A sinadder is really pretty simple. When I was using one, I never
paid much attention to the absolute readings in db and just used it as a
visual aid to tuning for minimum noise and distortion.

It sounds like the heater for one of the finals blew. Back when novices
were limited to 75 watts input, the way to do it was to remove one of the
finals (actually to remove the matched pair and put in a single 6146B,
then put the matched pair back in after upgrading).

Fellow amateurs.

Can I use a 12 volt deep-cycle marine battery to:

1. Power my HTX202? If so can I use the same guage wire that I use
with the gel cell? Pardon my ignorance but the battery is so big
compared to the HT. The battery runs the 12 volt system in the
camper.

2. Power my Radio Shack 30 watt power AMP? The AMP draws 6 amps
of current continous and I think the in-line fuse is
8 amps. I bought a regulated power supply from Radio Shack
that pops its breaker at 2.5 amps. It is ok for packet
but voice draws too much. The supply gives 13.8 VDC steady.
The battery would give probably 12.5 VDC and slowly drain off, obviously.
Any problem with that? Again does the guage of the wiring
make a difference?

Finally, I built a 2 meter ground-plane antenna from 12 guage wire
and a RO-239(?) connector. It works well off my HT, but would like
to use the AMP to it. Would 30 watt power hurt it? It has one
verticle radiator and two radials.

Absolutely No problem here, but I have been told to take off the battery pack
when using the 202 on External power. Seems to build up less heat.

> make a difference?
1st,
of course the amp will pop the breaker, it draws 6 amps, the supply is
rated at 2.5, not really a surprise. On Packet the transmissions are verry
short and the supply handles it, but either use a bigger supply or use the
battery you spoke of with a charger on it. (Even a small 2a trickle cosidering
the duty cycle you will probably run.)
2nd,
The wire does make a difference, and I wouldn't worry about the drop in
voltage. On the 202 all that does is lower the output power until the voltage
drops low enough to drop out the HT altogether. For wire I use polarized lamp
cord at 16 AWG. Good for 8-10 amps with no problem (again - duty % makes a
difference as well as length)
>Finally, I built a 2 meter ground-plane antenna from 12 guage wire

You have 1 radiator and 2 radials, I might add a third to bring it closer to
50ohms but it should work just great. Put it this way, it is a heck of a lot
better than a duck!

Yes. 12V is 12V regardless of where it comes from. The same gauge wire is
OK as well, since the HT will only draw as much current as it needs. But
it is *vital* to place a fuse or circuit breaker of a size apropriate for
the capacity of the wire right at the battery, so the high short-circuit
current of the large battery won't cause a fire in case of a short.

> Any problem with that? Again does the guage of the wiring
> make a difference?

This will work fine as well. The amp may not output quite as much power
with 12.5 V instead of 13.8, but it won't damage anything. The reason the
power supply works on packet is because the breaker is a thermal type that
does not trip instantly. You are drawing 6A from the supply (actually
less, since the voltage will drop) in either case, but the breaker doesn't
have time to open on packet. Wire of 16 gauge (what probably came with the
amp) is OK for short runs at the 8A level. It is important to keep the
wiring short so the voltage at the amp stays as high as possible. If the
wire must be more than a few feet long, consider going to 14, 12 or 10
gauge, not as a safety concern, but for higher performance. Again, the
fuse should be located right at the battery so any possible shorts in the
wiring will cause it to blow. The best way to tell if your wiring is
adequate is to measure the voltage at the amplifier and at the battery
while transmitting. If this test shows more than 0.5V or so drop, larger
wire will probably get you more RF output.

This will handle 30W just fine. I have used such antennas at the 100W level and they can probably handle much more. The thing to be careful of is to keep the antenna reasonably away (10' or more, but this is a trade-off with loss in the coax) from the rest of your hardware and 'wetware' when running high power. This is so the RF doesn't feed back in to low-level circuits and cause problems. Moving the antenna straight up is the best direction to take when moving it away.

>
Several possibilties:

(1) Something is wrong with the radio other than a bad final tube.
(2) One of the final tubes quit working, the other is fine.
(3) Both final tubes are down to about 50% of original capacity.

#1 is not too likely, assuming the power has dropped slowly as would be expected with a tube wearing out. But it could be the driver tube.
#2 is really unlikely, unless the heater or something else became open.
#3 seems most likely. The tubes are connected in parallel, so they should be replaced at the same time so they share the load equally.

As James suggests, you could test the tubes by trying them one at a time, or if it is the heater just look in and see that both light up. This will detect condition #2, but not differentiate #3 from #1. Another poster noted that the high voltage stays present for quite a while after switching off, and it's also important while running one tube not to let the plate lead for the other tube short out on anything. There is about 800 VDC and a lot of RF there. After opening the tube compartment (with the power unplugged, of course), discharge the tube plate caps (the terminal on top of the tube) to ground before touching them.

If you have #2 or #3, the cure is the same: two new tubes. Since they are connected in parallel, it's not a good idea to only change one as they won't share the load equally. Probably using pairs of tubes of the same brand, from the same manufacturer's lot would match well enough, although some places offer (at a higher price), "matched pairs". (As an aside, does anyone know what parameter is measured and 'matched' in these? Cutoff bias?)

Just running one tube in a circuit intended for two might put the driver plate/final grid circuit out of tune without the capacitance of the other tube's grid. Using two weak tubes would be about as good as one good one, and if that's enough to make the contacts you want to, you could stick with that. New tubes are only $12 - $20.00 each though so it's not a bad idea to start looking for a couple to use as replacements or spares. If you're on the rock-cheap budget plan, boxes of these tubes can sometimes be found used from low- (and even a few high-) band VHF commercial mobile radios. The part number 8298A is equivalent to 6146B. Plain 8298 (6146A) tubes have a lower power rating but might do OK in occasional use.

The only schematic I ever remember seeing in the Handbook with that tube was the "Self-Contained 500-Watt Transmitter" in the 1962 edition. The transmitter used a single 7094 for 500 watts CW input on 80-10M. The bias to the driver and final could be switched to Class AB1 for input of a low-level, on-frequency SSB signal.

I've recently purchased an older Wilson mobile/portable FM rig for my Land-Rover. Unfortunately, Wilson's idea of charging NiCd cells was to put them across the input 13.8 volt line sans regulation...ICK!

Anybody got a good suggestion for a chip-based NiCad charger circuit? Ideally, i'd like to just float the NiCad charging across the 12-volt auto bus and ignore it until I use the rig mobile...this way, they stay charged for the times Uncle Joe Lucas comes to visit (if you gotta ask, you'e never owned a British car...8*))

Waiting with bated breath - Alan/N1TWY

I have a few instruments which measure SINAD, including a Helper
Sinadder SL105, which is an RMS device. If you want to perform
industry standard SINAD sensitivity measurements, the 12 dB mark
becomes important. Too, I think the current EIA standard for land
mobile specifies an RMS SINAD measurement (vs. the average response
type of measurement available in the SL103 model).

SINAD measuring equipment can also be used to determine the modulation
acceptance of NBFM receivers.

BTW, Helper Instruments, maker of the Sinadder line of SINAD meters,
is still alive and well. They can furnish reprints of informative
articles on SINAD. Sorry, I don't have the address in front of me.
Helper used to advertise in Mobile Radio Technology but I don't
see their ads in most the recent issues.

> etc etc.
Let's see...

An older copy of the Handbook should have all the formulae to allow
you to calc the spacing for whatever impedance you want.

As for spreaders, Popsicle sticks used to make great spreaders when I
was a kid (L-O-N-G time ago! ;^) and there were several wrapping
methods in vogue. Again, a handbook would be a great information
source...
b
Zo = 276 log ---
a

Where:
b is the center-to-center distance between conductors
a is the radius of the conductor (same units as b)

The spreader fastening technique in teh 1959 Handbook is to drill a
small hole in the spreader for the fastening wire, and simply wrap the
fastening wire around the transmission line wire. Popsicle sticks
don't drill too well, so a groove at each end worked for me...

Good luck, and HAVE FUN!!!

Message-ID: <9509168138.AA813873166@mails.imed.com>
Source record: 110170

I just called AD to request that they do the only improvement that I think the AD7008 needs: It needs quadrature outputs for image reject receive mixers.

I got a request for the specs for the chip:

2 speed classes: 20 MHz and 50 MHz

on board sine and cosine lookup tables for doing I/Q stuff
two 10 bit multipliers and adder for doing I/Q stuff digitally

serial interface as well as either 8 bit or 16 bit parallel microprocessor interface

32 bit phase accumulator

2 frequency registers so you could for instance set both TX and RX frequencies and switch in one cycle from one to the other

a phase adjust register for doing direct phase modulation

As you can see this device is capable of simultaneously performing all three types of modulation(phase, frequency, and amplitude) all digitally!

They have a Fax Back number: (800)446-6212

request document number 1240, but be ready! It is 17 pages!

The biggest problem with the design in 73 magazine is that the author put all of the computer smarts on the same board as the DDS. If he had put the RF stuff on one board and the computer stuff on another it would allow for one RF design to be used in several system designs.

My favorite computer for control is a 8088 in minimum mode with one ROM and 1 SRAM and maybe an 8255 and 8250. This can be wire wrapped if desired and is still useful and for under $20 (I have a lot of ROMS in the junk box).

4711. DDS Article in 73

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-16 00:00:00 UTC
From: mack@mails.imed.COM
Message-ID: <9509168138.AA813869852@mails.imed.com>
Source record: 110171

There was a thread in one of the groups last week regarding the DDS article in October 1995 73 magazine. Someone on the list erroneously read the AD part of AD7008 as being an AMD part number. It isn't. It's an Analog Devices part. I just talked to Theresa at Allied in Corpus Christi. She said they are out of stock right now but the 20 MHz part is $28.20 in onsies and the 50MHz part is $33.85 in onsies.

I remember seeing the product announcement for the AD7008 last year but didn't pay a lot of attention because of the price at the time.

I don't know about y'all but I can't imagine a discreet design that I could make for $33.85. The cheapest 10 bit DAC is on the order of $50.00.

I took my 1994 AD design catalog home over the weekend to look at the part more closely. This looks like a REALLY nice part. It will do QAM digital modulation, phasing SSB, and other nifty things all digitally! The $5 price difference for the extra 15 MHZ out of the 50 MHz part (you can only get up to about 24 MHZ with the 50 MHZ clock part) seems like a really small difference.

>tgoins@accessone.com (Todd Goins) is trying to fix a commercial power supply
>that uses a 723 voltage regulator and a bunch of pass transistors.

In another life I used to repair medical equipment for a living. We had a +/-
15 power supply that used a 723 for each side of the power supply. It was my
experience that 100% (yes REALLY) of the failures of this supply were due to
some type of failure of this IC. A VERY common failure mode was for the 723 to
get REALLY squirrely and oscillate and other nasty manifestations. If you have
a 'scope, look at the output uder a light load with AC coupling and about
100mV/division. You might be surprised at what you see.

It didn't click until I saw someone else's post this morning that a supply using
this chip could very easily exhibit the output rise then fall symptoms
originally described. Any supply I owned that used this IC would have 2 or 3 of
these IC's sitting on the shelf as repair parts.

You can probably tell I am not especially fond of this IC. Consider that this
IC is one of the VERY first analog IC's from the late 60's or early 70's and
that there are many newer and better designed parts to choose from these days.

Jack---after many years of making open wire line, some with very strange impedances, I think I have found the most convient, and best spreader material possible! It is rather simple stuff when you think about it---air hose material used to transfer air from a manifold to an air gun! Usually, for no good reason it is yellow in color and retains a coiled shape when relaxed. Not that short lengths would matter. The best construction method is simply to burn a hole in the material some half inch from the ends of the cut off piece whose length you have already determined using log 276 b/a. Then slit the end back to the hole with a knife. Simply press in the spreader with the wire line, into the hole. Insulated or bare wire can be used, just change the size of the hole! Nothing has even come close to the longevity here on the ocean front than this system. luck with it 73 de Cliff W6HDO Morro Bay, CA

4716. re: Zenith Transoceanic

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-16 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <d00_9510162218@mba.mba.org>
Source record: 110176

Thom.LaCosta@f1352.n261.z1.fidonet.org (Thom LaCosta) wants
to build a bfo to fit inside his Zenith Transoceanic, and is
looking for a diagram.

This should be extremely easy to do. The most vital bit of
information that you need is the frequency of the IF strip, so
you can get the bfo on the right frequency. I would assume the
IF frequency is 455KHz, but that assumption is based on it being
a very common IF frequency in the old days. SOmebody with more
than passing interest in these old receivers should be able to
answer that question.

As for a circuit, the hills are alive with this sort of thing.
You basically want just a low power oscillator at the proper
frequency. Crystal control might be nice, but getting the crystal
can require a bit more work. I'm quite certain the IF response
of these receivers is not so great that the bfo has to be on an
exact point in the response, so the only value of a crystal controlled
bfo would be that it's stable, and it should be in the right place
without any tuning.

Any edition of the ARRL Handbook would have a circuit useable for this
project. Either in the form of a 455KHz oscillator meant for use
as a bfo, or a generic oscillator that could be applied to this use.

Similar circuits show up in Doug Demaw's less expensive ARRL books,
such as his Design Notebook.

They also show up over the years in plenty of magazines, for the
same purpose you need the bfo. To add one to a shortwave receiver
that doesn't have one. I haven't seen any published lately, though.

In a scheme like this, once you get the circuit built and going, you'll
need to get the signal into the receiver. I've seen articles doing
this that suggest just placing an oscillator at the right frequency
close to the receiver case, and there is enough injection. Putting
the BFO right inside the case, and hoping there is enough coupling,
might also work okay.

The best solution would be to directly couple the output of the bfo
into the receiver's detector. You'd need to trace out the circuitry
around the detector, or have a schematic to know where to inject.

If you start doing something this formally, you would do well
to add a switch to disable the agc line in the receiver.

stevem@w6yx.stanford.edu (Steve Muther) mentioned the lack of
stability in these old receivers, and that's true. There is a
way to get around this. Use a low power oscillator that operates
right on the signal frequency. Hopefully even without much work
you can build one more stable than the local oscillator of the
receiver. You would then tune the receiver to the signal you
want to listen to. Then tune the oscillator to that frequency,
and adjust for the right sound, ie the voice sounds right. This
way, the "bfo" is tuned to the incoming signal. The receiver might
move off frequency, but the only result would be a loss of sensitivity
as the signal moves down in the IF response. Your "BFO" is still
in the same place as the incoming signal (minus the required beat note),
so things are still in tune. The advantage of this method is that
you don't have to worry about coupling to the detector. You do
want a quite low power oscillator, since it will be amplified in
the receiver along with the incoming signal. Making it's output
level variable might be useful. You also don't want the "bfo" to
start radiating out in to space, since then you might end up
interfering with other stations.

Hope this helps.

Yes. The load (the radio) determines the size of the wire needed.
Since the '202 draws abt 1 amp on high power transmit, light guage wire
will be OK on either power source.

Physical size of the battery isn't the concern...voltage is. The
larger battery will last longer (a lot longer, most of the time.)

It will work fine.

> Any problem with that? Again does the guage of the wiring
> make a difference?

Depends on the length of the run from the amp to the battery. The
longer the run, the larger guage of wire you need to reduce voltage
drop.

No, the output of the amp will not hurt the ground plane. Make sure
you have a good match (SWR) between the amp, or the protection circuit
of the amp will shut down the amp.

Curious...why didn't you add the other two radials?

Hi,
I have a Kenwood TS-830 shortwave TRX. This rig has two 6146B
as final tubes. But from another OM I got two 6146W from
GEC (General Electric Canada) instead.
Nobody of our amateur radio clubs could tell me the difference
between the B and the W suffix and if I could replace them
or not. Could you give me any hints ?

Greetings from Switzerland

>_____
>Ron Cruikshank
G'day Ron. Daycom (03) 9543 6444 have 450 ohm ladder line.

However, if you want to make your own open wire line; cut up some 1/8" or 1/4" thick perspex into rectangles, about 1 X 2" . You will need sufficient for one spacer each 24" or so of line.

Drill a 1/16" hole through each end of the rectangle, about 1/8" from each end.

Using a triangular file, form a well-defined v-groove in the centre of each end (corresponding to the 1/16" hole).

Obtain some plain copper wire (not insulated), about # 14 gauge (try non-ferrous metal merchants). Measure out a pair, of required length. No kinks.

Anchor one end of the pair to a solid object, about 1 or 2 feet above ground.

Tie the other end of the pair to the tow-ball of your car.

Use the vehicle to impart just sufficient tension to remove the wrinkles, and maintain a nice tension on the pair. Hand-brake & Park.

One at a time, insert you spacers between the pair so that the spacer is held captive between the v-grooves. Use a single strand of plain #18 copper wire threaded through each 1/16" hole to hold the pair onto the spacer. Wrap the wire around each side, and solder. Repeat for the number of spacers required.

You could probably achieve better results using a DDS instead of a PLL synth. There have been DDS articles in QST and 73 recently. These would easily triple up to the 6-meter band.

Why not insulated, other than it's harder to detect breaks?
I prefer to use insulated for both feedlines and antennas;
less corrosion and rain static.

4728. Recommendation for a good "Grid Dipper"

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-17 00:00:00 UTC
From: forrerj@ucs.orst.edu
Message-ID: <461aff$h3o@news.orst.edu>
Source record: 110188

Hi All,

I am looking for a professional quality "grid-dipper". Essentially it should have better than average sensitivity and good operating range from say 1 - 500 Mhz (switched ranges/coil packs are OK too). Price is not an object (within reason of course).

This is for remotely detecting the resonance frequency of a passive resonator - remote means a couple of inches away from the resonant circuit which is inaccessable, though not shielded.

I would be most grateful if anyone could recommend a manufacturer/source for such an instrument.

Much thanks,

Johan Forrer, KC7WW

>
Jeff,

I found the following info on the 15520*A* in the Tucker catalog:

Freq: 45-95 MHz
Range of return loss measurement: 0 to 40 dB.
Loss between input and side ports: 6 dB.
Loss between output and side ports: 6 dB.
Minimum balance: 56 dB.
Impedance: 75 ohms
Maximum input power: +20 dBm
BNC(F) connectors

I don't know what the differences are between A and C models, but there's a good chance that they're very similar.

Good Luck,

Jon

4731. 2N7000's: important information

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-17 00:00:00 UTC
From: wayne@interval.com
Message-ID: <wayne-1710952151230001@burdick.interval.com>
Source record: 110191

This is important reading for designers and kit builders about a component that has recently become popular in QRP circles. [Please publish widely.]

The 2N7000 is a DMOS MOSFET transistor that is great for switching uses: it can be used just like an NPN transistor, but requires no current-limit or bias resistor at the base lead (its gate lead draws no current). In fact, in the TO-92 package, its leads are in the same order as a bipolar transistor: S-G-D correspond to E-B-C.

BUT: this part *IS* subject to static damage. Before you handle one, sit down and touch the nearest metal surface that is grounded (rig, scope ground lead, etc.).

Several recent club and commercial kits use 2N7000s. Hopefully, those who pack the kits make sure that their 2N7000 transistors are good when they go into the anti-static bags--after that it's up to the builder. 99% of the time, you won't have a problem even if you handle them improperly (see story at the end of the article). It's the 1% I'm trying to eliminate.

This is a very useful part that won't go away, so here are some strongly recommended guidelines:

1. NEVER buy surplus 2N7000s or similar parts unless they are still on or in their protective anti-static shipping material. Loose parts in bins must be 100% tested before use.

2. NEVER remove them from the shipping material until you're properly grounded. It is then OK to put them into anti-static bags but NOT into ordinary plastic bags.

3. If you suspect one is bad, you can tentatively substitute a 2N2222A or other NPN transistor for it in many cases, BUT you must add a resistor (typically 10K) in series with the base lead. This is necessary because in most circuits, the 2N7000 is driven directly by things like microprocessor output pins, and you'll fry the NPN transistor without base current limiting.

Now, just to confuse the issue, here's an amusing counter-example:

When I designed the 2N7000s into a recent project, I attempted to do "destructive testing" of one of the parts. I held a 2N7000 loosely in my hand, scuffed my feet around on carpet, rubbed the part on my cat, shocked myself on the sliding glass door transistor-first, and other things too horrible to mention. Then I put it back in the circuit. It still worked! Perhaps some of the parts are better than others! After all, they are made by more than one manufacturer.

Hope this clarifies the use of these devices. Assume the worst, despite my good luck with one of them.

73,
Wayne Burdick
N6KR

4732. Re: Silver vs. Nickel: Why?

Newsgroup: rec.radio.amateur.homebrew

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

The real reason for using silver plated connectors below UHF is not electrical performance. The silver connectors will take solder flow well and require less heating and have better wetting characteristics. The use of teflon-silver connectors will insure a good job every time and no shorted, melted wasted connectors. The silver teflon connectors are available at Radio Shack (2 PL-259's per package). Most Ham dealers have them and others. Your time in assembly and debugging makes the extra 50ï¿½ worth it every time.

>purchasing a balanced to unbalanced adaptor.

Likely true in many cases, but properly doing the balanced to unbalanced conversion with a transformer at the rig also gets rid of pesky common mode *RF* pickup as well as stray field AC hum. *That* can be important in many ham shacks. With a short mike cable, and good RF bypassing at the rig input, you can usually get away with just tying mike low to ground, but using the transformer is the right way to do it, and can solve RF feedback problems.

>as possible with minimal parts count, I'd prefer to avoid the extra
>hardware if not essential.

It would be good practice to use a line driver and a line receiver
chip at each end of the link. Going directly to the low current
micro's pins invites noise and spike problems. A line driver/receiver
pair will source/sink enough current to offer decent immunity to
induced noise currents. Differential driver/receivers may be overkill
here, but they don't cost much more. Or you could even opticouple
with a pair of H111 chips. They're dirt cheap, and insure that any
voltage on the wires can't get to the sensitive (and expensive)
chips.

Yes, I do know that. I designed a marine radio that worked that way
20 years ago. However, you don't want to operate the VCO on the transmit
frequency because of feedback problems.

>I'm operating the PLL/VCO at half the required frequency and running it
>through 1 doubler stage within the radio. The doubled frequency runs
>through a bandpass filter, spurs are not an big issue.

That's a good architecture, but it exceeds the frequency range of the '157.

The main thing is to get enough air over the filament pins. Heat can
take the temper out of the filament contact springs and eventually the
pin will desolder or the base will crack.

Message-ID: <463sck$kf2@pacific.mps.ohio-state.edu>
Source record: 110202
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

As I recall, the 6146B should not be used in circuits intended for the 6146 or 6146A. In addition to having higher plate dissipation, the 6146B requires a higher screen voltage to obtain the same operating point. Therefore, if a 6146B is plugged into, e.g., a Viking Ranger, it won't have enough screen voltage to maintain the same power output as a 6146/A. At least that's what I recall from years ago when the 6146B was first released. Someone pse tell me if I"m wrong!

> Is Eimac still in business?

Despite gross and appalling mismanagement by Varian, Eimac survived and is now owned by the same company that owns Victoria's Secret. So you can get tube sockets and boob sockets from the same source! They do not usually sell to the public (that policy is not cast in concrete) but you can buy their products from distributors like Richardson Electronics in Chicago. But you can call Eimac directly at: 415-592-1221 for a list of distributors. Prepare yourself for sticker shock on socket prices. Fair Radio in Lima, Ohio, Slep Electronics in Otto, NC, and many others often market used or surplus sockets at much lower prices.

I found exactly the same problem. The VCO radiation is so strong
that it affected the operation of the PLL. It created reference spurs
on either side of the VCO out past 200kHz. I was able to fabricate
a shield over the VCO, including the PC inductor, that reduced the
spurs to an acceptable level.

The receiver has very little front end selectivity, and I was plagued
with pager intermod. I was able to replace the front end "tuned"
circuit with a Toko two-section helical filter. Now I don't have
the intermod problem, and the sensitivity seems about the same
(not measured but using off the air signals).

>Tell me what you know about 40m verticals, I've been told that ground
>radials acutally function better above ground. I want to build the best
>40m vertical I can. What do you have to share?

Hi Tim,

The most important ingredient is a good ground conductivity. I used a
vertical on fourty at the seashore, it worked great, whereas inland it
was very poor. If you live inland you may be better with a horizontally
polarized antenna (inverted vee, quad loop...) suspended from the highest
pole you can put up.

My (portable) antenna was a slightly shortened (7 meters) 1/4 wl radiator
and 3 to 4 radials, with the feed point about 10 meters above ground.
If you have the feed point at ground level, you need a very large
number (100) of radials. There were simulations published by Al Christman,
indicating that 4 radials a little (1/10 wl) above ground work as well
as 100 on the ground, but these results are heavily disputed.

I personally think you are being a bit paranoid, 11m linears are so
plentiful and easy to get many hams are now buying them and cleaning
them up to use on 12 and 15, sometimes even 20. If the person is
interested in building one, he probably isn't planning on just using it
for a kicker for his CB, those are easy enough to get.

just my $.02 worth.

>Home Page: http://www.primenet.com/~lager

Try Ham Radio Outlet on Camelback. They have carried the silver plated
connectors in the past. They are usually easier to solder than the
nickel plated ones. The connectors they carry are probably a better
quality than Radio Shack carries.

Hi Tim OM,

If you want to build the best vertical you can, then build a half wave vertical dipole, and elevated it as far above ground as you can. You need no ground whatsoever with a halfwave vertical antenna. It can be fed in the same way as VHF verticals like the J are fed: at the end with a quarter wave stub or a tuned tank circuit (same thing electrically), or at the center via a 1:1 balun. It can also be center or end fed, of course, with tuned feeders.

bb840@scn.org (James Aeschliman) wrote:

>It sounds like the heater for one of the finals blew.

Not sure about the 'S, but my '520 runs the heaters in SERIES,
therefore it's an "all or nothing" situation on the final filiments.
(guess they did this so that inverter would not need to handle
filiment current when mobile.)

This was very bad design practice on Kenwood's part. Positive temp co
devices (heaters) can be unstable when in series. Also, it sacrifices
the advantage of redundancy.

BTW, by the time '520 came along, Novices were allowed 250W DC input
power. (this was the new rig on mkt when I was a Novice). Pulling
one final would require adding a resistor to simulate other tubes
filiment. And why not just load it back anyway...There never was a
reg that said your equiptment couldn't be capable of more power...Even
a single 6146 would be illeagal (90W input) if so. My DX-60B manual
advises novices to load back it's lone '46 so as to be under the 75
limit. Guess you would save filiment time on second final...but they
used to be pretty cheap in those days. If someone actually did this,
please tell me why.

Back on thread:

It is possible that one tube has shorted out all or part of its
filiment, leaving it cold, and the other super hot. You should be
able to see this without opening the PA "doghouse".

More likely a bad connection to one tube..open inductor resistor or
some such.. Loss of vacum maybe also.
Could be HV supply lost a diode as well.

If HV level is normal, then you could lift one plate cap at a time and
see which one kills it completely. Then switch tubes and see if it
moves with the tube or not. If not, then look at wiring, if so , then
just a bad tube. Note: pulling one tube out will kill both, if
filiments are in series as in '520

---> CAUTION: High Voltage! <----

BTW '520 does NOT require matched finals. Just don't mix '46 ,'46A or
'46B, because filiment resistance varies, and they won't "share"
filiment power equally. But if one died, might as well do both...its
only another 30 bucks or so, but no more hassel..all those screws,
neutralizing etc....I hate to leave a weak link anyway. Would

probably do the driver while I was in there too, as it would have similar filiment time as finals.

I brought a basket case '520 back from the grave (prev owner had already begun scavaging parts) so know my way around it pretty well. e-mail me (others welcome too) if you want opinions/advice.

4763. Johnson Ranger II Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-19 00:00:00 UTC
From: James Garland <garland@ohstpy.mps.ohio-state.edu>
Message-ID: <466g8m$qqr@pacific.mps.ohio-state.edu>
Source record: 110084

My "new" Ranger II seems to work fine (about 45 watts output), but the power transformer seems to run awfully hot -- not too hot to hold my hand on, but nearly so. It's a large transformer, considering the modest power level of the transmitter, so I'm puzzled. I measured all the voltages and they seem normal, but I suppose it's possible something is drawing too much current that I'm not aware of. Does anyone else notice the same thing? Jim W8ZR

4764. -=-=-Blackout's Box-=-=-

Greetings everybody.

Well some of you know me, and some of you don't - but I'm Blackout,
and the box is backup, although at a pretty lame location.

1-800-KOOK-LINE (1-800-566-5546)
ext 345

If you're new to the game, Blackout's Box is an underground crank line
and I suppose you could say it is somewhat like the jerky boys but
much better as the calls are all real and not staged.

This one is on a lame company vmb that only goes up after 6 p.m.
though... temporarily untill I find a better vmb to continue the
tradition of the box on.

If anyone out there has a better vmb.. one that can have LOOOONNG
greeting msgs.. one that is on an 800 number with multiple lines...
and one that has GOOD sound quality and not crappy compression sound, and
you would like to help out the box cause.. let me know.

Sometimes I update the message every night... sometimes once a week..
whenever inspiration strikes.

Peace... and creative chaos to all!

Blackout

I'm curious how the VCO radiation is affecting the operation of the
PLL. Certainly the reference spurs are expected as a result of leakthrough
in the loop filter; are the spurs much higher than you expect? Did you
check the loop filter to make sure it was working correctly?

Yeah, there's apparently way too much gain in the front end
with way too little selectivity. I'm surprised it works as
well as it does.

4768. Want to jam stupid radio station

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-19 00:00:00 UTC
From: ez041502@dale.ucdavis.edu
Message-ID: <464rnm$885@mark.ucdavis.edu>
Source record: 110089

Is this possible? I'd only want to jam one particular signal in a small area. I don't know if this'll help me pick up the station I like, which happens to be right next to it, but I'd like to jam it just out of spite. And yes, I'm sure the FCC isn't going to approve.
Stan Kwong

4769. DDS Article in 73

Hi Bill...speaking of using DDS' on the air...
Do you have any good wideband amp designs to get the milliwatt signal
up around the watt or 2 range ? (Must be 12 volt design).
There was an article in 73 magazine a couple of years back called
the "Technowhizzy"...it used a Qualcomm DDS along with a 1 or 2 watt
wideband amp but apparently the amp design was a flop (how it made it to
print is beyond me !?).
I'm dying to get my Harris based DDS on the air for QRP work !

Thanks..Hugh VA3TO

The radio remains intact...I just inject the VCO signal further up the
line.
Hmmm... the '157 I have here is running at 26 Mhz !!

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control

> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,

myself included. If you wanna make love to yourself, do so in private !
